"Applicability", DNR proposes that this rule apply ONLY to Class II injection wells, not to any other. DNR has not proposed any rules for fracking wells. This is insufficient protection of the population in southern Illinois where citizens are at risk of a major earthquake. Southern Illinois sits above two active seismic zones: the New Madrid and the Wabash Valley. There are two distinct earthquake risks: (1) the risks from injection wells inducing earthquakes that would not otherwise occur and (2) the risks of substantial injuries and damages created when the toxic fracking fluid left in the ground, in pipelines, and in wells (injection and otherwise) is let loose as a result of a major earthquake. There are NO rules establishing guidelines for stopping fracking wells in the event of earthquakes, and NO considerations for siting any wells specifically in active seismic zones. That omission is a reckless disregard for the safety of Southern Illinois residents, their property, and the ecology of the region. Furthermore, in light of recent studies (see below), the risk of earthquakes can extend far beyond local areas. See: <http://www.earth.columbia.edu/articles/view/3072> : A new study is the latest to tie a string of unusual earthquakes, in this case, in central Oklahoma, to the injection of wastewater deep underground. Researchers now say that the magnitude 5.7 earthquake near Prague, Okla., on Nov. 6, 2011, may also be the largest ever linked to wastewater injection. Felt as far away as Milwaukee, more than 800 miles away, the quake—the biggest ever recorded in Oklahoma--destroyed 14 homes, buckled a federal highway and left two people injured. <http://geology.gsapubs.org/content/early/2013/03/26/G34045.1> <http://www.usgs.gov/newsroom/article.asp?ID=3706&from=rss#.UohRF40hRL8> "Why America's Heartland is Earthquake Country", United States Geological Service, September 30, 2013 "Enhanced Remote Earthquake Triggering at Fluid-Injection Sites in the Midwestern United States", Nicholas J. van der Elst et al., DOI: 10.1126/science.1238948, Science 341, 164 (2013).

Researchers now say that the magnitude 5.7 earthquake near Prague, Okla., on Nov. 6, 2011, may also be the largest ever linked to wastewater injection. Felt as far away as Milwaukee, more than 800 miles away, the quake—the biggest ever recorded in Oklahoma--destroyed 14 homes, buckled a federal highway and left two people injured. <http://geology.gsapubs.org/content/early/2013/03/26/G34045.1> <http://www.usgs.gov/newsroom/article.asp?ID=3706&from=rss#.UohRF40hRL8> "Why America's Heartland is Earthquake Country", United States Geological Service, September 30, 2013 "Enhanced Remote Earthquake Triggering at Fluid-Injection Sites in the Midwestern United States", Nicholas J. van der Elst et al., DOI: 10.1126/science.1238948, Science 341, 164 (2013).

In reference to Part 240: Seismicity

Section 240.796 Seismicity In subsection (a)

"Applicability", DNR proposes that this rule apply ONLY to Class II injection wells, not to any other. DNR has not proposed any rules for fracking wells. This is insufficient protection of the population in southern Illinois where citizens are at risk of a major earthquake. Southern Illinois sits above two active seismic zones: the New Madrid and the Wabash Valley. There are two distinct earthquake risks: (1) the risks from injection wells inducing earthquakes that would not otherwise occur and (2) the risks of substantial injuries and damages created when the toxic fracking fluid left in the ground, in pipelines, and in wells (injection and otherwise) is let loose as a result of a major earthquake. There are NO rules establishing guidelines for stopping fracking wells in the event of earthquakes, and NO considerations for siting any wells specifically in active seismic zones. That omission is a reckless disregard for the safety of Southern Illinois residents, their property, and the ecology of the region. Furthermore, in light of recent studies (see below), the risk of earthquakes can extend far beyond local areas. See: <http://www.earth.columbia.edu/articles/view/3072> : A new study is the latest to tie a string of unusual earthquakes, in this case, in central Oklahoma, to the injection of wastewater deep underground. Researchers now say that the magnitude 5.7 earthquake near Prague, Okla., on Nov. 6, 2011, may also be the largest ever linked to wastewater injection. Felt as far away as Milwaukee, more than 800 miles away, the quake—the biggest ever recorded in Oklahoma--destroyed 14 homes, buckled a federal highway and left two people injured. <http://geology.gsapubs.org/content/early/2013/03/26/G34045.1> <http://www.usgs.gov/newsroom/article.asp?ID=3706&from=rss#.UohRF40hRL8> "Why America's Heartland is Earthquake Country", United States Geological Service, September 30, 2013 "Enhanced Remote Earthquake Triggering at Fluid-Injection Sites in the Midwestern United States", Nicholas J. van der Elst et al., DOI: 10.1126/science.1238948, Science 341, 164 (2013).

That omission is a reckless disregard for the safety of Southern Illinois residents, their property, and the ecology of the region. Furthermore, in light of recent studies (see below), the risk of earthquakes can extend far beyond local areas. See:

<http://www.earth.columbia.edu/articles/view/3072> : A new study is the latest to tie a string of unusual earthquakes, in this case, in central Oklahoma, to the injection of wastewater deep underground. Researchers now say that the magnitude 5.7 earthquake near Prague, Okla., on Nov. 6, 2011, may also be the largest ever linked to wastewater injection. Felt as far away as Milwaukee, more than 800 miles away, the quake—the biggest ever recorded in Oklahoma--destroyed 14 homes, buckled a federal highway and left two people injured. <http://geology.gsapubs.org/content/early/2013/03/26/G34045.1>

In reference to Part 240: Seismicity

Section 240.796 Seismicity In subsection (a)

"Applicability", DNR proposes that this rule apply ONLY to Class II injection wells, not to any other. DNR has not proposed any rules for fracking wells. This is insufficient protection of the population in southern Illinois where citizens are at risk of a major earthquake. Southern Illinois sits above two active seismic zones: the New Madrid and the Wabash Valley. There are two distinct earthquake risks: (1) the risks from injection wells inducing earthquakes that would not otherwise occur and (2) the risks of substantial injuries and damages created when the toxic fracking fluid left in the ground, in pipelines, and in wells (injection and otherwise) is let loose as a result of a major earthquake. There are NO rules establishing guidelines for stopping fracking wells in the event of earthquakes, and NO considerations for siting any wells specifically in active seismic zones. That omission is a reckless disregard for the safety of Southern Illinois residents, their property, and the ecology of the region. Furthermore, in light of recent studies (see below), the risk of earthquakes can extend far beyond local areas. See: <http://www.earth.columbia.edu/articles/view/3072> : A new study is the latest to tie a string of unusual earthquakes, in this case, in central Oklahoma, to the injection of wastewater deep underground. This is insufficient protection of the population in southern Illinois where citizens are at risk of a major earthquake. Southern Illinois sits above two active seismic zones: the New Madrid and the Wabash Valley. There are two distinct earthquake risks: (1) the risks from injection wells inducing earthquakes that would not otherwise occur and (2) the risks of substantial injuries and damages created when the toxic fracking fluid left in the ground, in pipelines, and in wells (injection and otherwise) is let loose as a result of a major earthquake. There are NO rules establishing guidelines for stopping fracking wells in the event of earthquakes, and NO considerations for siting any wells specifically in active seismic zones. That omission is a reckless disregard for the safety of Southern Illinois residents, their property, and the ecology of the region. Furthermore, in light of recent studies (see below), the risk of earthquakes can extend far beyond local areas. See: <http://www.earth.columbia.edu/articles/view/3072> : A new study is the latest to tie a string of unusual earthquakes, in this case, in central Oklahoma, to the injection of wastewater deep underground. Researchers now say that the magnitude 5.7 earthquake near Prague, Okla., on Nov. 6, 2011, may also be the largest ever linked to wastewater injection. Felt as far away as Milwaukee, more than 800 miles away, the quake—the biggest ever recorded in Oklahoma--destroyed 14 homes, buckled a federal highway and left two people injured. <http://geology.gsapubs.org/content/early/2013/03/26/G34045.1> <http://www.usgs.gov/newsroom/article.asp?ID=3706&from=rss#.UohRF40hRL8> "Why America's Heartland is Earthquake Country", United States Geological Service, September 30, 2013 "Enhanced Remote Earthquake Triggering at Fluid-Injection Sites in the Midwestern United States", Nicholas J. van der Elst et al., DOI: 10.1126/science.1238948, Science 341, 164 (2013).

In reference to Subpart A: General Provisions

### Section 245.100 Applicability

245.100 Applicability Problem: The draft rules (Sec. 245.100) apply only to fracking operations occurring since June 17, 2013, while the original regulatory act clearly mandates that the provisions in the act apply to past, current, and future wells. Specifically, Section 1-20 of the Hydraulic Fracturing Regulatory Act passed earlier this year states that the Act “applies to all wells where high volume horizontal hydraulic fracturing operations are planned, have occurred, or are occurring in this State”. The existence and presumed necessity of the rules is clear evidence that unregulated fracking poses a significant risk to the health and safety of Illinois citizens and their environment. Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

Sincerely, B. E. Murphy 458 Tahoe Park Forest, IL 60466

### Section 245.100 Applicability

How, IDNR, do you flout the law passed by the General Assembly? Let me count the ways. As the public agency charged with protecting the environment and the public's health from the dangers of hydraulic fracturing, why would you limit your power to regulate the hydraulic fracturing within the state on purpose? Let me remind you that Section 1-20 of the Hydraulic Fracturing Regulatory Act "applies to all wells where high volume horizontal hydraulic fracturing operations are planned, have occurred, or are occurring in this State." In short, that's ALL the wells and ALL of the activities that occurred there. However, the draft rules (Sec. 245.100) apply only to fracking operations occurring since June 17, 2013. Why???? Clearly the obvious necessity of the General Assembly's act and of the subsequent hydraulic fracturing regulations (written by IDNR) are enough proof that unregulated hydraulic fracturing operations pose a risk to the health and safety of Illinois' citizens and the environment. (Why bother writing them if the activity posed no risk?) So again, why would you want to limit the scope of the rules when in fact older wells may require greater regulation given age and lack of regulation regarding their original construction? All hydraulic fracturing companies should report "high volume hydraulic fracturing" activities, regardless of when the activity occurred. IDNR should ensure that all operations, including past operations, comply(idd) with the regulations outlined by IDNR to the furthest extent possible, requiring compliance with air emissions control requirements associated with production, post-frack testing and reporting, and other obligations that protect public and environmental health.

Sincerely, Sara Buck Chicago , IL 60640

Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

Sincerely, Mary Ellen Barbezat Elgin, IL 60120

### Section 245.100 Applicability

Problem: The draft rules (Sec. 245.100) apply only to fracking operations occurring since June 17, 2013, while the original regulatory act clearly mandates that the provisions in the act apply to past, current, and future wells. Specifically, Section 1-20 of the Hydraulic Fracturing Regulatory Act passed earlier this year states that the Act “applies to all wells where high volume horizontal hydraulic fracturing operations are planned, have occurred, or are occurring in this State”. The existence and presumed necessity of the rules is clear evidence that unregulated fracking poses a significant risk to the health and safety of Illinois citizens and their environment. Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

Sincerely, Ammar Kalimullah Chicago, IL 60637

### Section 245.100 Applicability

The draft rules (Sec. 245.100) apply only to fracking operations occurring since June 17, 2013, while the original regulatory act clearly mandates that the provisions in the act apply to past, current, and future wells. Specifically, Section 1-20 of the Hydraulic Fracturing Regulatory Act passed earlier this year states that the Act “applies to all wells where high volume horizontal hydraulic fracturing operations are planned, have occurred, or are occurring in this State”. The existence and presumed necessity of the rules is clear evidence that unregulated fracking poses a significant risk to the health and safety of Illinois citizens and their environment. Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

### Section 245.100 Applicability

The draft rules (Sec. 245.100) apply only to fracking operations occurring since June 17, 2013, while the original regulatory act clearly mandates that the provisions in the act apply to past, current, and future wells. Specifically, Section 1-20 of the Hydraulic Fracturing Regulatory Act passed earlier this year states that the Act “applies to all wells where high volume horizontal hydraulic fracturing operations are planned, have occurred, or are occurring in this State”. The existence and presumed necessity of the rules is clear evidence that unregulated fracking poses a significant risk to the health and safety of Illinois citizens and their environment. Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

Sincerely, Dylon Busser Chicago, IL 60647

### Section 245.100 Applicability

The draft rules (Sec. 245.100) apply only to fracking operations occurring since June 17, 2013, while the original regulatory act clearly mandates that the provisions in the act apply to past, current, and future wells. Specifically, Section 1-20 of the Hydraulic Fracturing Regulatory Act passed earlier this year states that the Act “applies to all wells where high volume horizontal hydraulic fracturing operations are planned, have occurred, or are occurring in this State”. The existence and presumed necessity of the rules is clear evidence that unregulated fracking poses a significant risk to the health and safety of Illinois citizens and their environment. Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. In reference to Subpart A: General Provisions

### Section 245.100 Applicability

The draft rules (Sec. 245.100) apply only to fracking operations occurring since June 17, 2013, while the original regulatory act clearly mandates that the provisions in the act apply to past, current, and future wells. Specifically, Section 1-20 of the Hydraulic Fracturing Regulatory Act passed earlier this year states that the Act “applies to all wells where high volume horizontal hydraulic fracturing operations are planned, have occurred, or are occurring in this State”. The existence and presumed necessity of the rules is clear evidence that unregulated fracking poses a significant risk to the health and safety of Illinois citizens and their environment. Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

Sincerely, Jasha Sommer-Simpson Chicago, IL 60615

The existence and presumed necessity of the rules is clear evidence that unregulated fracking poses a significant risk to the health and safety of Illinois citizens and their environment. Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

Sincerely, Kathy Machaj Chicago, IL 60607

### Section 245.100 Applicability

The draft rules (Sec. 245.100) apply only to fracking operations occurring since June 17, 2013, while the original regulatory act clearly mandates that the provisions in the act apply to past, current, and future wells. Specifically, Section 1-20 of the Hydraulic Fracturing Regulatory Act passed earlier this year states that the Act “applies to all wells where high volume horizontal hydraulic fracturing operations are planned, have occurred, or are occurring in this State”. The existence and presumed necessity of the rules is clear evidence that unregulated fracking poses a significant risk to the health and safety of Illinois citizens and their environment. Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

Sincerely, maayan olshan Chicago, IL 60615

In reference to Subpart A: General Provisions

### Section 245.100 Applicability

The draft rules (Sec. 245.100) apply only to fracking operations occurring since June 17, 2013, while the original regulatory act clearly mandates that the provisions in the act apply to past, current, and future wells. Specifically, Section 1-20 of the Hydraulic Fracturing Regulatory Act passed earlier this year states that the Act “applies to all wells where high volume horizontal hydraulic fracturing operations are planned, have occurred, or are occurring in this State”. The existence and presumed necessity of the rules is clear evidence that unregulated fracking poses a significant risk to the health and safety of Illinois citizens and their environment. Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

### Section 245.100 Applicability

The draft rules (Sec. 245.100) apply only to fracking operations occurring since June 17, 2013, while the original regulatory act clearly mandates that the provisions in the act apply to past, current, and future wells. Specifically, Section 1-20 of the Hydraulic Fracturing Regulatory Act passed earlier this year states that the Act “applies to all wells where high volume horizontal hydraulic fracturing operations are planned, have occurred, or are occurring in this State”. The existence and presumed necessity of the rules is clear evidence that unregulated fracking poses a significant risk to the health and safety of Illinois citizens and their environment. Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

Sincerely, Scott Condren Chicago, IL 60608

### Section 245.100 Applicability

The draft rules (Sec. 245.100) apply only to fracking operations occurring since June 17, 2013, while the original regulatory act clearly mandates that the provisions in the act apply to past, current, and future wells. Specifically, Section 1-20 of the Hydraulic Fracturing Regulatory Act passed earlier this year states that the Act “applies to all wells where high volume horizontal hydraulic fracturing operations are planned, have occurred, or are occurring in this State”. The existence and presumed necessity of the rules is clear evidence that unregulated fracking poses a significant risk to the health and safety of Illinois citizens and their environment. Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

### Section 245.100 Applicability

The draft rules (Sec. 245.100) apply only to fracking operations occurring since June 17, 2013, while the original regulatory act clearly mandates that the provisions in the act apply to past, current, and future wells. Specifically, Section 1-20 of the Hydraulic Fracturing Regulatory Act passed earlier this year states that the Act “applies to all wells where high volume horizontal hydraulic fracturing operations are planned, have occurred, or are occurring in this State”. The existence and presumed necessity of the rules is clear evidence that unregulated fracking poses a significant risk to the health and safety of Illinois citizens and their environment. Hence, it makes no sense for IDNR to intentionally limit the scope of the rules to apply only to new fracking operations, while bypassing regulations on old wells. One might even argue that older wells—given both their age and the lack of regulations at the time of their construction—would merit greater attention from regulatory agencies. Revisions Needed: Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc.

### Section 245.100 Applicability

To the Illinois Department of Natural Resources, My name is Rebecca Quesnell and I am twenty years old. Although I have only had twenty years of life I have taken note that a lot of companies, factories, etcetera have been grandfathered into exemptions. I request that this does not occur with already existing hydraulic fracturing sites in Illinois. In the drafted rules released by you, the IDNR, Sec. 245.100 applies only to fracking operations occurring since June 17, 2013. However, the original regulatory act very clearly mandates that the provisions in the act apply to past, present, and future hydraulic fracturing wells. More specifically, Sec. 1-20 of the Hydraulic Fracturing Regulatory Act passed earlier this year states that the Act “applies to all wells where high volume horizontal hydraulic fracturing operations are planned, have occurred, or are occurring in this State”. It seems to me that the existence and presumed necessity of the rules is clear evidence that unregulated fracking poses a significant risk to the health and safety of Illinois citizens and their environment. Let’s face it, even regulated fracking poses great risks, especially in Southern Illinois given the known fault lines that will be drilled near and that could definitely be triggered by the occurring fracking in the area. Thus, it makes absolutely no sense for the IDNR to INTENTIONALLY limit the scope of the rules to apply to only new fracking operations and, in the process, bypassing regulations for and on old wells! To be completely honest, it is likely that older wells (given their age and the lack of regulations at the time of their construction) merit even greater attention from regulatory agencies (meaning you!) because of the risk they pose to both peoples’ health and the environment! I just cannot believe that this is yet another loophole that has been created within these proposed rules and regulations. They should not even be called rules and regulations because you are not looking at regulating fracking from every perspective and direction. As a result of this very noticeable loophole (for older frack sites) I urge you to revise this thought process and section of the rules and regulations. I ask that you: 1. Require all fracking companies to report any prior fracking activities that fall under the definition of “high volume hydraulic fracturing”, regardless of when the activity occurred. 2. Ensure that past operations comply with the regulations outlined by IDNR to the furthest extent possible. For example, while it would not make sense for an operator to go back and re-perform drilling activities that did not conform to the Act, it should require compliance of ongoing obligations mandated by the rules – such as air emissions control requirements associated with production, post-frack testing and reporting, etc. Thank you for your time in reading this, and please consider what I have discussed and stop giving loopholes to fracking companies!

Sincerely, Rebecca Quesnell 3 Talisman Trace Galena, IL 61036

### Section 245.110 Definitions

"Affected Patient" Proposed Administrative Rules- Hydraulic Fracturing Regulatory Act The definition of Affected Patient refers to "illness or injury diagnosed by the health care professional to be caused by exposure to any chemicals used in high volume horizontal hydraulic fracturing operations that are subject to a claim of trade secret by a permittee or contractor." This reference to trade secret chemicals is in direct contradiction to the federal law, Occupational Health and Safety Act of 1970. According to this law, workplaces are mandated to post all chemicals that a worker may be exposed to on the job, as well as what to do in the case of exposure. It is imperative that this information be available freely and immediately, and OSHA inspectors will fine an employer for noncompliance. The regulation's treatment of fracking chemicals, many of which are deadly and/or carcinogenic such as benzene and other solvents, as "trade secret" is totally unconscionable and should be struck. When it comes to exposure to toxic chemicals, DNR should be looking out for public safety and not some false notion of private business practices. Your standard cannot violate federal law, please mandate that all fracking chemicals must be explicitly stated- with no provision for redaction of "trade secrets"- and provided not only as part of the initial permit application to DNR and before beginning operation (as specified in 245.700) but on a consistent basis as a matter of essential public knowledge, especially when it comes to health professionals and "affected patients" and to people living in surrounding communities. "Trade secrets" should not be allowed to come before public safety and again, I urge you to remove the provision entirely.

Sincerely, Ivy Czekanski 601 W. Deming Place #502 Chicago, IL 60614

### Section 245.110 Definitions

According to IDNR's definitions, a "Well site" means surface areas, including the surface location of the well, occupied by all equipment or facilities necessary for, or incidental to, high volume horizontal hydraulic fracturing operations, construction, drilling, production, or plugging a well. (Section 1-5 of the Act) While this definition might be appropriate for a well that drills straight down, as wells once did, it is not appropriate for horizontal hydraulic fracturing wells. Horizontal hydraulic fracturing operations involve an initial drilling site that then grows to include horizontal legs radiating out from the site. Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. This definition is critical because setback requirements are based on IDNR's inadequate definition of a well-site when they should, at a minimum, be based on the distance from any part of the well, including all underground horizontal legs of the well. To adopt the current definition of well site is to apply an old understanding about what constitutes a well to an approach to drilling that has grown much more complex. The IDNR needs to reflect its understanding of the inherent and possible dangers of hydraulic fracturing by recognizing that the well site for such an operation has much greater breadth than the current definition envisions.

Sincerely, Aija Nemer-Aanerud Chicago, IL 60615

(Section 1-5 of the Act) While this definition might be appropriate for a well that drills straight down, as wells once did, it is not appropriate for horizontal hydraulic fracturing wells. Horizontal hydraulic fracturing operations involve an initial drilling site that then grows to include horizontal legs radiating out from the site. Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. This definition is critical because setback requirements are based on IDNR's inadequate definition of a well-site when they should, at a minimum, be based on the distance from any part of the well, including all underground horizontal legs of the well. To adopt the current definition of well site is to apply an old understanding about what constitutes a well to an approach to drilling that has grown much more complex. The IDNR needs to reflect its understanding of the inherent and possible dangers of hydraulic fracturing by recognizing that the well site for such an operation has much greater breadth than the current definition envisions.

Sincerely, Alex Farrenkopf Chicago, IL 60637

Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. This definition is critical because setback requirements are based on IDNR's inadequate definition of a well-site when they should, at a minimum, be based on the distance from any part of the well, including all underground horizontal legs of the well. To adopt the current definition of well site is to apply an old understanding about what constitutes a well to an approach to drilling that has grown much more complex. The IDNR needs to reflect its understanding of the inherent and possible dangers of hydraulic fracturing by recognizing that the well site for such an operation has much greater breadth than the current definition envisions.

Sincerely, Anna Woolery Chicago, IL 60637

### Section 245.110 Definitions

According to IDNR's definitions, a "Well site" means surface areas, including the surface location of the well, occupied by all equipment or facilities necessary for, or incidental to, high volume horizontal hydraulic fracturing operations, construction, drilling, production, or plugging a well. (Section 1-5 of the Act) While this definition might be appropriate for a well that drills straight down, as wells once did, it is not appropriate for horizontal hydraulic fracturing wells. Horizontal hydraulic fracturing operations involve an initial drilling site that then grows to include horizontal legs radiating out from the site. Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. This definition is critical because setback requirements are based on IDNR's inadequate definition of a well-site when they should, at a minimum, be based on the distance from any part of the well, including all underground horizontal legs of the well. To adopt the current definition of well site is to apply an old understanding about what constitutes a well to an approach to drilling that has grown much more complex. The IDNR needs to reflect its understanding of the inherent and possible dangers of hydraulic fracturing by recognizing that the well site for such an operation has much greater breadth than the current definition envisions.

Sincerely, Brian Menzel Chicago, IL 60608

### Section 245.110 Definitions

According to IDNR's definitions, a "Well site" means surface areas, including the surface location of the well, occupied by all equipment or facilities necessary for, or incidental to, high volume horizontal hydraulic fracturing operations, construction, drilling, production, or plugging a well. (Section 1-5 of the Act) While this definition might be appropriate for a well that drills straight down, as wells once did, it is not appropriate for horizontal hydraulic fracturing wells. Horizontal hydraulic fracturing operations involve an initial drilling site that then grows to include horizontal legs radiating out from the site. Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. This definition is critical because setback requirements are based on IDNR's inadequate definition of a well-site when they should, at a minimum, be based on the distance from any part of the well, including all underground horizontal legs of the well. To adopt the current definition of well site is to apply an old understanding about what constitutes a well to an approach to drilling that has grown much more complex. The IDNR needs to reflect its understanding of the inherent and possible dangers of hydraulic fracturing by recognizing that the well site for such an operation has much greater breadth than the current definition envisions.

Sincerely, Elias Friedman Chicago, IL 60605

### Section 245.110 Definitions

According to IDNR's definitions, a "Well site" means surface areas, including the surface location of the well, occupied by all equipment or facilities necessary for, or incidental to, high volume horizontal hydraulic fracturing operations, construction, drilling, production, or plugging a well. (Section 1-5 of the Act) While this definition might be appropriate for a well that drills straight down, as wells once did, it is not appropriate for horizontal hydraulic fracturing wells. Horizontal hydraulic fracturing operations involve an initial drilling site that then grows to include horizontal legs radiating out from the site. Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. This definition is critical because setback requirements are based on IDNR's inadequate definition of a well-site when they should, at a minimum, be based on the distance from any part of the well, including all underground horizontal legs of the well. To adopt the current definition of well site is to apply an old understanding about what constitutes a well to an approach to drilling that has grown much more complex. The IDNR needs to reflect its understanding of the inherent and possible dangers of hydraulic fracturing by recognizing that the well site for such an operation has much greater breadth than the current definition envisions.

Sincerely, Glen Edward Litchfield Darien, IL 60561

### Section 245.110 Definitions

According to IDNR's definitions, a "Well site" means surface areas, including the surface location of the well, occupied by all equipment or facilities necessary for, or incidental to, high volume horizontal hydraulic fracturing operations, construction, drilling, production, or plugging a well. (Section 1-5 of the Act) While this definition might be appropriate for a well that drills straight down, as wells once did, it is not appropriate for horizontal hydraulic fracturing wells. Horizontal hydraulic fracturing operations involve an initial drilling site that then grows to include horizontal legs radiating out from the site. Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. This definition is critical because setback requirements are based on IDNR's inadequate definition of a well-site when they should, at a minimum, be based on the distance from any part of the well, including all underground horizontal legs of the well. To adopt the current definition of well site is to apply an old understanding about what constitutes a well to an approach to drilling that has grown much more complex. The IDNR needs to reflect its understanding of the inherent and possible dangers of hydraulic fracturing by recognizing that the well site for such an operation has much greater breadth than the current definition envisions.

Sincerely, John Hunt Chicago, IL 60641

### Section 245.110 Definitions

According to IDNR's definitions, a "Well site" means surface areas, including the surface location of the well, occupied by all equipment or facilities necessary for, or incidental to, high volume horizontal hydraulic fracturing operations, construction, drilling, production, or plugging a well. (Section 1-5 of the Act) While this definition might be appropriate for a well that drills straight down, as wells once did, it is not appropriate for horizontal hydraulic fracturing wells. Horizontal hydraulic fracturing operations involve an initial drilling site that then grows to include horizontal legs radiating out from the site. Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. This definition is critical because setback requirements are based on IDNR's inadequate definition of a well-site when they should, at a minimum, be based on the distance from any part of the well, including all underground horizontal legs of the well. To adopt the current definition of well site is to apply an old understanding about what constitutes a well to an approach to drilling that has grown much more complex. The IDNR needs to reflect its understanding of the inherent and possible dangers of hydraulic fracturing by recognizing that the well site for such an operation has much greater breadth than the current definition envisions.

Sincerely, Kevin Casto Chicago, IL 60615

### Section 245.110 Definitions

According to IDNR's definitions, a "Well site" means surface areas, including the surface location of the well, occupied by all equipment or facilities necessary for, or incidental to, high volume horizontal hydraulic fracturing operations, construction, drilling, production, or plugging a well. (Section 1-5 of the Act) While this definition might be appropriate for a well that drills straight down, as wells once did, it is not appropriate for horizontal hydraulic fracturing wells. Horizontal hydraulic fracturing operations involve an initial drilling site that then grows to include horizontal legs radiating out from the site. Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. This definition is critical because setback requirements are based on IDNR's inadequate definition of a well-site when they should, at a minimum, be based on the distance from any part of the well, including all underground horizontal legs of the well. To adopt the current definition of well site is to apply an old understanding about what constitutes a well to an approach to drilling that has grown much more complex. The IDNR needs to reflect its understanding of the inherent and possible dangers of hydraulic fracturing by recognizing that the well site for such an operation has much greater breadth than the current definition envisions.

Sincerely, Matthew Raigosa Chicago, IL 60608

### Section 245.110 Definitions

According to IDNR's definitions, a "Well site" means surface areas, including the surface location of the well, occupied by all equipment or facilities necessary for, or incidental to, high volume horizontal hydraulic fracturing operations, construction, drilling, production, or plugging a well. (Section 1-5 of the Act) While this definition might be appropriate for a well that drills straight down, as wells once did, it is not appropriate for horizontal hydraulic fracturing wells. Horizontal hydraulic fracturing operations involve an initial drilling site that then grows to include horizontal legs radiating out from the site. Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. This definition is critical because setback requirements are based on IDNR's inadequate definition of a well-site when they should, at a minimum, be based on the distance from any part of the well, including all underground horizontal legs of the well. To adopt the current definition of well site is to apply an old understanding about what constitutes a well to an approach to drilling that has grown much more complex. The IDNR needs to reflect its understanding of the inherent and possible dangers of hydraulic fracturing by recognizing that the well site for such an operation has much greater breadth than the current definition envisions.

Sincerely, Noah Hellermann New York, IL 11218

### Section 245.110 Definitions

According to IDNR's definitions, a "Well site" means surface areas, including the surface location of the well, occupied by all equipment or facilities necessary for, or incidental to, high volume horizontal hydraulic fracturing operations, construction, drilling, production, or plugging a well. (Section 1-5 of the Act) While this definition might be appropriate for a well that drills straight down, as wells once did, it is not appropriate for horizontal hydraulic fracturing wells. Horizontal hydraulic fracturing operations involve an initial drilling site that then grows to include horizontal legs radiating out from the site. Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. This definition is critical because setback requirements are based on IDNR's inadequate definition of a well-site when they should, at a minimum, be based on the distance from any part of the well, including all underground horizontal legs of the well. To adopt the current definition of well site is to apply an old understanding about what constitutes a well to an approach to drilling that has grown much more complex. The IDNR needs to reflect its understanding of the inherent and possible dangers of hydraulic fracturing by recognizing that the well site for such an operation has much greater breadth than the current definition envisions.

### Section 245.110 Definitions

According to IDNR's definitions, a "Well site" means surface areas, including the surface location of the well, occupied by all equipment or facilities necessary for, or incidental to, high volume horizontal hydraulic fracturing operations, construction, drilling, production, or plugging a well. (Section 1-5 of the Act) While this definition might be appropriate for a well that drills straight down, as wells once did, it is not appropriate for horizontal hydraulic fracturing wells. Horizontal hydraulic fracturing operations involve an initial drilling site that then grows to include horizontal legs radiating out from the site. Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. This definition is critical because setback requirements are based on IDNR's inadequate definition of a well-site when they should, at a minimum, be based on the distance from any part of the well, including all underground horizontal legs of the well. To adopt the current definition of well site is to apply an old understanding about what constitutes a well to an approach to drilling that has grown much more complex. The IDNR needs to reflect its understanding of the inherent and possible dangers of hydraulic fracturing by recognizing that the well site for such an operation has much greater breadth than the current definition envisions.

Sincerely, sam zacher Chicago, IL 60637

### Section 245.110 Definitions

According to IDNR's definitions, a "Well site" means surface areas, including the surface location of the well, occupied by all equipment or facilities necessary for, or incidental to, high volume horizontal hydraulic fracturing operations, construction, drilling, production, or plugging a well. (Section 1-5 of the Act) While this definition might be appropriate for a well that drills straight down, as wells once did, it is not appropriate for horizontal hydraulic fracturing wells. Horizontal hydraulic fracturing operations involve an initial drilling site that then grows to include horizontal legs radiating out from the site. Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. This definition is critical because setback requirements are based on IDNR's inadequate definition of a well-site when they should, at a minimum, be based on the distance from any part of the well, including all underground horizontal legs of the well. To adopt the current definition of well site is to apply an old understanding about what constitutes a well to an approach to drilling that has grown much more complex. The IDNR needs to reflect its understanding of the inherent and possible dangers of hydraulic fracturing by recognizing that the well site for such an operation has much greater breadth than the current definition envisions.

Sincerely, Tim Dompke Collinsville, IL 62224

### Section 245.110 Definitions

According to IDNR's definitions, a "Well site" means surface areas, including the surface location of the well, occupied by all equipment or facilities necessary for, or incidental to, high volume horizontal hydraulic fracturing operations, construction, drilling, production, or plugging a well. (Section 1-5 of the Act) While this definition might be appropriate for a well that drills straight down, as wells once did, it is not appropriate for horizontal hydraulic fracturing wells. Horizontal hydraulic fracturing operations involve an initial drilling site that then grows to include horizontal legs radiating out from the site. Leaks or ruptures, the well's proximity to water sources, and/or to real property are not adequately imagined by the well site definition that underpins so much of the IDNR's approach to these regulations. The well site definition should be expanded to include the surface area above any and all horizontal or vertical legs of the well. The current narrow definition does not adequately protect the health, safety and well-being of Illinois citizens, nor will it adequately sequester water used for human or animal consumption from accidents that can occur anywhere the drilling occurs. A useful way of thinking of a hydraulic fracturing well site would be to compare it to an iceberg, where the small amount of ice visible at the water's surface gives no hint of the size of the area occupied by the iceberg below the water line. The potential surface area that can be detrimentally affected by a hydraulic fracturing operation includes all land within 500, 750, or 1500 feet of a hydraulic fracturing leg (to use the IDNR's own measurements), regardless of the leg's horizontal or vertical relationship to the earth. ### Section 245.110 Definitions

As a person who has earned a Bachelors of Science in Biology, I know that aquatic biology is extremely diverse and complex. Section 245.110 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: "Aquatic life" means all fish, reptiles, amphibians, crayfish, and mussels. However, these macroscopic animals are not all that matters when it comes to aquatic and how the health of that life effects the health of nearby humans. For instance, not even a plant definition of aquatic life is included, and yet, without the photosynthesizing members of the aquatic community, macroscopic species such as fish and mussels would be unable to survive. This definition is too narrow and does not include many other species that may be important to an aquatic ecosystem. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Specific scientific standards must be developed to include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Sincerely, Harry Li 2656 Boddington Lane Naperville, IL 60564

### Section 245.110 Definitions

As a person who has earned a Bachelors of Science in Biology, I know that aquatic biology is extremely diverse and complex. Section 245.110 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: "Aquatic life" means all fish, reptiles, amphibians, crayfish, and mussels. However, these macroscopic animals are not all that matters when it comes to aquatic and how the health of that life effects the health of nearby humans. For instance, not even a plant definition of aquatic life is included, and yet, without the photosynthesizing members of the aquatic community, macroscopic species such as fish and mussels would be unable to survive. This definition is too narrow and does not include many other species that may be important to an aquatic ecosystem. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Specific scientific standards must be developed to include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Sincerely, Harry Li 2656 Boddington Lane Naperville, IL 60564

### Section 245.110 Definitions

Comment: IDNR identifies the definition of an "Affected patient" as "a person receiving health care services from a health professional for an illness or injury diagnosed by the health professional to be caused by exposure to any chemicals used in high volume horizontal hydraulic fracturing operations that are subject to a claim of trade secret by a permittee or contractor." PROBLEM – This definition is circular: in order to learn what chemical was used, a physician must first test for it so he can prove he has a right to disclosure of the proprietary chemical. How can a doctor diagnose exposure to a secret chemical used in high volume fracking before he knows which chemicals to test for?

Sincerely, Abby Dompke Chicago, IL 60607

### Section 245.110 Definitions

Comment: IDNR identifies the definition of an "Affected patient" as "a person receiving health care services from a health professional for an illness or injury diagnosed by the health professional to be caused by exposure to any chemicals used in high volume horizontal hydraulic fracturing operations that are subject to a claim of trade secret by a permittee or contractor." PROBLEM – This definition is circular: in order to learn what chemical was used, a physician must first test for it so he can prove he has a right to disclosure of the proprietary chemical. How can a doctor diagnose exposure to a secret chemical used in high volume fracking before he knows which chemicals to test for?

Sincerely, Cindy Chung Chicago, IL 60637

### Section 245.110 Definitions

Comment: IDNR identifies the definition of an "Affected patient" as "a person receiving health care services from a health professional for an illness or injury diagnosed by the health professional to be caused by exposure to any chemicals used in high volume horizontal hydraulic fracturing operations that are subject to a claim of trade secret by a permittee or contractor." PROBLEM – This definition is circular: in order to learn what chemical was used, a physician must first test for it so he can prove he has a right to disclosure of the proprietary chemical. How can a doctor diagnose exposure to a secret chemical used in high volume fracking before he knows which chemicals to test for?

Sincerely, Joey Knotts Chicago, IL 60605

### Section 245.110 Definitions

Comment: IDNR identifies the definition of an "Affected patient" as "a person receiving health care services from a health professional for an illness or injury diagnosed by the health professional to be caused by exposure to any chemicals used in high volume horizontal hydraulic fracturing operations that are subject to a claim of trade secret by a permittee or contractor." PROBLEM – This definition is circular: in order to learn what chemical was used, a physician must first test for it so he can prove he has a right to disclosure of the proprietary chemical. How can a doctor diagnose exposure to a secret chemical used in high volume fracking before he knows which chemicals to test for? Let's illustrate the amount of chemicals we are discussing here. After all, a picture is worth a thousand words! The imaginary Frack Family at their Beaver County home, showing off the 757 barrels of chemicals used to frack the well near their house - including 373 barrels of "mystery" chemicals. Comment: IDNR identifies the definition of an "Affected patient" as "a person receiving health care services from a health professional for an illness or injury diagnosed by the health professional to be caused by exposure to any chemicals used in high volume horizontal hydraulic fracturing operations that are subject to a claim of trade secret by a permittee or contractor." PROBLEM – This definition is circular: in order to learn what chemical was used, a physician must first test for it so he can prove he has a right to disclosure of the proprietary chemical. How can a doctor diagnose exposure to a secret chemical used in high volume fracking before he knows which chemicals to test for?

Sincerely, Reed Mershon Chicago, IL 60637

### Section 245.110 Definitions

Comment: IDNR identifies the definition of an "Affected patient" as "a person receiving health care services from a health professional for an illness or injury diagnosed by the health professional to be caused by exposure to any chemicals used in high volume horizontal hydraulic fracturing operations that are subject to a claim of trade secret by a permittee or contractor." PROBLEM – This definition is circular: in order to learn what chemical was used, a physician must first test for it so he can prove he has a right to disclosure of the proprietary chemical. How can a doctor diagnose exposure to a secret chemical used in high volume fracking before he knows which chemicals to test for?

Sincerely, Yvette McGivern Chicago, IL 60637

### Section 245.110 Definitions

Ecosystem: "An ecosystem is a system which is formed when a community of organisms interacts with the environment. An ecosystem is basically an organism community which interacts with one another and their environment in such a way that energy is transferred between them and system-level processes like the cycle of elements emerge. The ecosystem is the core concept in Ecology and Biology, and serves as the building block of biological organization where organisms interact with each other simultaneously and with the environment as well. Therefore, ecosystems are a step after the ecological community level ( in which organisms of different species interact with one another) and are at a stage below or equal to the biosphere and biomes. Essentially, they are regional ecosystems, while the biosphere is larger than all the possible ecosystems." From: <http://www.ecosystem.org> For this reason, it doesn't make any sense that Section 245.110 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules defines "Aquatic life" as all fish, reptiles, amphibians, crayfish, and mussels. Such a narrow definition excludes many other species important to an aquatic ecosystem. As can be extrapolated from the definition above, freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, and minerals/gases (e.g. oxygen), for example. Focusing on such an exclusive definition of "aquatic life" unnecessarily removes focus from numerous important elements of the larger ecosystem to focus on a few components of the ecosystem. Often other, smaller organisms/ecological changes reflect negative ecological effects of human activities long before the larger creatures in an ecosystem show signs of danger. In other words, the canary dies before the miners do, a la the canary in the mineshaft. IDNR rules must broaden the rules to include "aquatic ecosystems", rather than "aquatic life." Specific scientific standards for the protection of aquatic ecosystems within the rules should include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Sincerely, Sara Buck Chicago , IL 60640

### Section 245.110 Definitions

How are healthcare providers supposed to provide treatment to patients whose lives or health are in danger due to exposure to fracking chemicals when they do not have access to the identities of the chemicals used in the process? Comment: IDNR identifies the definition of an "Affected patient" as "a person receiving health care services from a health professional for an illness or injury diagnosed by the health professional to be caused by exposure to any chemicals used in high volume horizontal hydraulic fracturing operations that are subject to a claim of trade secret by a permittee or contractor." PROBLEM – This definition is circular: in order to learn what chemical was used, a physician must first test for it so he can prove he has a right to disclosure of the proprietary chemical. How can a doctor diagnose exposure to a secret chemical used in high volume fracking before he knows which chemicals to test for? With over 350 proprietary chemicals used in the fracking process, using screening tests to determine which chemical is involved in order to determine treatment is not only wasteful of healthcare resources, both in terms of time and money, but also potentially and unnecessarily puts people's lives at risk.

Sincerely, Ken Buck Naperville, IL 60540

### Section 245.110 Definitions

I am a resident of Jackson County living on a piece of land that was once owned by a coal company. I am also very sensitive to volatile organic compounds which trigger awful asthma attacks. The rules protecting the trade secrets of these caustic chemicals in the fracking process have a strong potential for damaging my health. Over the years, I've witnessed mine subsidence all over Southern IL and we are also sitting smack dab on the New Madrid fault. Currently, the Big Muddy is at Flood stage and a week ago, torrential rain fall happened with flash flooding. What I don't see are meaningful penalties or any decision makers with addresses in the lower 17 counties of IL where fracking is most likely to occur. You need a native on that board who knows about the mine subsidence down state. You need the voice of down state residents who have homes and health directly affected by fracking.

Sincerely, Paula Cade 213 Janet Lane Murphysboro, IL 62966

### Section 245.110 Definitions

I grew up in eastern Kansas before moving to Illinois. One of my dearest childhood memories is the unencumbered view from my back porch--wheat fields broken up by trees clustered around the occasional stream for as far as the eye can see. My grandparents lived not too far from where we lived. I loved working in my grandmother's garden. She prided herself on her roses and her asparagus bed. We played tag in her backyard with all of the neighbor kids, and at the end of a long round of play, my grandfather would make homemade ice cream or my grandmother would bring out lemonade. For the fourth of July, my grandparents would buy \$300 worth of fireworks, which we would light in the yard. When the fireworks weren't there to entertain us, we would chase fireflies. Imagine how this all would have changed if a well rig suddenly appeared in our back yard? Or if a well bore malfunctioned and poisoned the land on which my grandparents lived, killing her roses and asparagus? What if it appeared in my backyard, where I sled down into the field behind the house? How would that have affected my childhood? Would you let your children run around a well rig? Would you put your children at risk for polluted food and water? Wouldn't you want a choice in the matter? While I now have lived in Illinois for more than 15 years, I can't imagine giving up those memories. Even when I lived in Senegal as a Peace Corps volunteer, I looked out onto the savannah and thought fondly of my childhood in Kansas. This is why I can't understand why IDNR would propose rules do not require a permit applicant to demonstrate having acquired the property-owner's consent to drill a vertical well in a proposed location. Just as equally bizarre, rules do not require a permit applicant to demonstrate having acquired consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled. The rules don't even require notice to these property owners. Section 245.110 of IDNR's proposed rules redefine real property rights in a manner inconsistent with current Illinois property law. The proposed rules create an entirely new legal term called "real property surface interest," which flouts Illinois law. According to Illinois law, even when the property owner no longer maintains mineral rights, he or she does not necessarily forgo all rights to the subsurface. Secondly, the concept of "real property surface interest" narrows the concept of property owner to simply the surface (as opposed to the term owner of real property" used in Illinois law), excluding the idea that a property owner owns the surface AND subsurface and also excluding the idea that any property owner controls interest in the subsurface. IDNR's rules should be revised by deleting the definition of "real property surface interest" in Section 245.110. In addition, Section 245.210(A)(16)(A) & (B) should be revised to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Lastly, Section 245.250(a)(1)(A) should be revised to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Sara Buck Chicago , IL 60640

### Section 245.110 Definitions

IDNR identifies the definition of an "Affected patient" as "a person receiving health care services from a health professional for an illness or injury diagnosed by the health professional to be caused by exposure to any chemicals used in high volume horizontal hydraulic fracturing operations that are subject to a claim of trade secret by a permittee or contractor." PROBLEM – This definition is circular: in order to learn what chemical was used, a physician must first test for it so he can prove he has a right to disclosure of the proprietary chemical. How can a doctor diagnose exposure to a secret chemical used in high volume fracking before he knows which chemicals to test for?

### Section 245.110 Definitions

It is irresponsible for planners of the state to consider allowing fracking in areas that are prone to tornadoes, without creating adequate rules that will protect citizens from the toxic flow back water. It is not safe to allow gas companies to frack in Illinois. Not only are these companies destroying fresh, drinking water in a world that continues to lack access to drinking water, but they haven't even established proper means to ensure that this toxic flow back water is stored properly to prevent contaminations. The possibilities of this toxic water being out in the open in a land prone to tornadoes - where debris from tornadoes are found over 150 miles from where the tornado is - are disastrous and dangerous to all Illinois residents. I urge you to please reconsider allowing fracking in our state. It is unsafe and dangerous to our health and environment.

Sincerely, Carolyn Brunsen Chicago, IL 60605

### Section 245.110 Definitions

It's directly dangerous to the health of Illinois citizens to allow fracking close to their homes. There have been recorded health problems in every single state where fracking has taken place so far, and these are huge health problems we're talking about. There are cancers and chronic headaches and nosebleeds. People are getting cancer just from living in their homes. They've lived there for years without any problems, but within a few months of the gas companies coming in and setting up fracking wells they have huge, expensive, incurable health problems. These problems can drive families out of their homes. Do you really intend to give the gas companies more of a right to citizen's homes than the families that have lived there for years? It is irresponsible to allow fracking in Illinois, when we know how dangerous the process is. I urge you to stop this before you put citizens at risk.

Sincerely, Virginia Baker 2007 S BLUE ISLAND AVE APT 3F CHICAGO, IL 606082928

### Section 245.110 Definitions

Number of draft regulations proposed by Illinois Dept. of Natural Resources describing safety measures regarding tornado strikes on fracking sites: ZERO. Number of tornadoes in Illinois in the last 10 years: 674. Historically, the number and intensity of tornadoes in Illinois is very high. "In fact, Illinois has experienced some of the worst tornadoes in US history." Dr. Jim Angel, Illinois State Climatologist. Every county in Illinois has had multiple tornadoes as demonstrated by the maps in the following links:

<http://www.isws.illinois.edu/atmos/statecli/tornado/ilmaps.htm>

<http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/IL-Tornadoes-13-1995.png> A big swath of Washington, IL was flattened by a tornado on Sunday, 11/17/13. What would have happened if this tornado had hit an area of the state covered in fracking sites? Debris from the tornado has been found over 150 miles away. Imagine if that debris had included "temporarily" stored flowback water or tanks filled with frack fluid or produced water!

### Section 245.110 Definitions

Relevant parts of the Proposed Administrative Rules: 245.110 Definitions Comment: IDNR identifies the definition of an "Affected patient" as "a person receiving health care services from a health professional for an illness or injury diagnosed by the health professional to be caused by exposure to any chemicals used in high volume horizontal hydraulic fracturing operations that are subject to a claim of trade secret by a permittee or contractor." PROBLEM – This definition is circular: in order to learn what chemical was used, a physician must first test for it so he can prove he has a right to disclosure of the proprietary chemical. Of the 1000 barrels of fracking chemicals used on a site, 350 will be "mystery barrels" due to the trade secrets law. How can a doctor diagnose exposure to a secret chemical used in high volume fracking before he knows which chemicals to test for? Full disclosure of chemicals used at a site must be available to physicians upon request. Trade secret rules must not trump public safety.

Sincerely, Andrew Panelli 12051 Mackinac Rd Homer Glen, IL 60491

### Section 245.110 Definitions

#### Rules Deprive Property Owners of Their Property Rights Without Notice and Without Compensation

How does this affect me: Who is in control Relevant parts of the Proposed Administrative Rules: Subpart A: General Provisions (245.100-245.120)245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law.

Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Janet McDonnell 1322 North Vail Avenue Arlington Heights, IL 60004

### Section 245.110 Definitions

Section 245.110 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: "Aquatic life" means all fish, reptiles, amphibians, crayfish, and mussels. Problems with this section: \* This definition is too narrow and does not include many other species that may be important to an aquatic ecosystem. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. \* Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: \* Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. \* By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. \* It neglects the biological criteria for the protection of aquatic life. Revisions Needed: \* The definition of "aquatic life" must be broadened to include "aquatic ecosystems". \* Specific scientific standards must be developed to include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Section 245.110 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states:

“Aquatic life” means all fish, reptiles, amphibians, crayfish, and mussels. Problems with this section: 1.

This definition is too narrow and does not include many other species that may be important to an aquatic ecosystem. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. 2. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants),

micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: 1.

Exclusively focusing on a limited definition of “aquatic life” unnecessarily narrows the impact to the

larger ecosystem that sustains it. 2. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. 3. It neglects the biological criteria

for the protection of aquatic life. Revisions Needed: 1. The definition of “aquatic life” must be

broadened to include “aquatic ecosystems”. 2. Specific scientific standards must be developed to

include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Sincerely, Karina Hendren Chicago, IL 60637

### Section 245.110 Definitions

Section 245.110 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: "Aquatic life" means all fish, reptiles, amphibians, crayfish, and mussels. Problems with this section: This definition is extremely narrow and does not include many other plant, animal and micro-organism species that are important to an aquatic ecosystem. Might one also want to include shorebirds, mammals and insects? Illinois' waterways form a migratory path for Canadian Geese and various ducks for instance, another management area of IDNR, one would have thought. Alterations in water quality impacts plants (and sometimes oxygenation), and then the rest of the system. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Additionally, the soils and geology around an aquatic ecosystem factor into the water chemistry and quality, and the life in it. Toxic substances, alterations in the terrain, temperature, climate, are additional variables. The issue: Exclusively focusing on a limited definition of "aquatic life" overlooks or ignores the impact to the larger ecosystem that sustains it. By the time a fish kill occurs, pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Specific scientific standards must be developed to include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Specific scientific standards must be developed to include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Sincerely, Ammar Kalimullah Chicago, IL 60637

### Section 245.110 Definitions

Section 245.110 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: "Aquatic life" means all fish, reptiles, amphibians, crayfish, and mussels. Problems with this section: This definition is too narrow and does not include many other species that may be important to an aquatic ecosystem. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Specific scientific standards must be developed to include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Sincerely, Brian Menzel Chicago, IL 60608

### Section 245.110 Definitions

Section 245.110 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: "Aquatic life" means all fish, reptiles, amphibians, crayfish, and mussels. Problems with this section: This definition is too narrow and does not include many other species that may be important to an aquatic ecosystem. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Specific scientific standards must be developed to include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Sincerely, Dylan Busser Chicago, IL 60647

### Section 245.110 Definitions

Section 245.110 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: "Aquatic life" means all fish, reptiles, amphibians, crayfish, and mussels. Problems with this section: This definition is too narrow and does not include many other species that may be important to an aquatic ecosystem. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Problems with this section: This definition is too narrow and does not include many other species that may be important to an aquatic ecosystem. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Specific scientific standards must be developed to include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Sincerely, Jan A Pietrzak 12031 S 72nd Ct Palos Heights, IL 60463

### Section 245.110 Definitions

Section 245.110 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: "Aquatic life" means all fish, reptiles, amphibians, crayfish, and mussels. Problems with this section: This definition is too narrow and does not include many other species that may be important to an aquatic ecosystem. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Specific scientific standards must be developed to include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Sincerely, Katie Lettie Chicago, IL 60637

Section 245.110 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: "Aquatic life" means all fish, reptiles, amphibians, crayfish, and mussels. Problems with this section: This definition is too narrow and does not include many other species that may be important to an aquatic ecosystem. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Specific scientific standards must be developed to include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Sincerely, Mansi Kathuria Chicago, IL 60647

Problems with this section: This definition is too narrow and does not include many other species that may be important to an aquatic ecosystem. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of “aquatic life” unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of “aquatic life” must be broadened to include “aquatic ecosystems”. Specific scientific standards must be developed to include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Sincerely, Rachel Katz Chicago, IL 60615

### Section 245.110 Definitions

Section 245.110 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: "Aquatic life" means all fish, reptiles, amphibians, crayfish, and mussels. Problems with this section: This definition is too narrow and does not include many other species that may be important to an aquatic ecosystem. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Specific scientific standards must be developed to include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Sincerely, Rui Chicago, IL 60637

### Section 245.110 Definitions

Section 245.110 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, states: "Aquatic life" means all fish, reptiles, amphibians, crayfish, and mussels. Problems with this section: This definition is too narrow and does not include many other species that may be important to an aquatic ecosystem. Aquatic life cannot be understood apart from the larger aquatic ecosystem which sustains it. Freshwater ecosystems (limnology) not only include fauna, but also flora (plants), micro/macro invertebrates, oxygen levels and algae, for example. Why these are problems: Exclusively focusing on a limited definition of "aquatic life" unnecessarily narrows the impact to the larger ecosystem that sustains it. By the time a fish kill occurs pollution caused by fracking will have reached a critical stage, causing havoc across the larger ecosystem. It neglects the biological criteria for the protection of aquatic life. Revisions Needed: The definition of "aquatic life" must be broadened to include "aquatic ecosystems". Specific scientific standards must be developed to include: a) Biological standards, b) High quality water resources, c) Modified or limited water resources, and d) Stressor identification.

Sincerely, Ta Promlee Chicago, IL 60645

### Section 245.110 Definitions

Section 245.110 With the dying loons effected by botulism from the Goby fish, I believe more stress on the ecology of the Great Lake watersheds could threaten our drinking water, recreational fishing and hunting as well as disrupt bird migrations. This language is too limited and when fracking produces fish kills it will be too late, creating havoc on the larger ecosystem. The definition of aquatic life must include aquatic ecosystems to provide regulatory direction to keep our lakes and rivers viable. We cannot support one industry over the ruination of others - tourism etc. to say nothing of viable drinking water and the irrigation for farmlands.

Sincerely, Katharine 3240 N Lakeshore Dr (Apt 15 B) Chicago, IL 60657

### Section 245.110 Definitions

Subpart A: General Provisions (245.100-245.120) 245.110 Definitions The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, B. E. Murphy 458 Tahoe Park Forest, IL 60466

Subpart A: General Provisions (245.100-245.120) 245.110 Definitions The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Brendan F. Houlihan 12217 S. 68th Ct. Palos Heights,, IL 60463-1607

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

---

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Abby Dompke Chicago, IL 60607

The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Anne Pertner Pertner Chicago, IL 60605

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

---

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Bob Venier Dixon, IL 61021

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. ### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

---

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Cindy Chung Chicago, IL 60637

The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, David Klawitter Chicago, IL 60607

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Dylan Busser Chicago, IL 60647

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Eve Zuckerman Chicago, IL 60615

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Gianna Chacon Chicago, IL 60605

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

---

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Jay Chicago, IL 60637

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon
