total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Jessica Green Chicago, IL 60637

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Jorge Sanchez Chicago, IL 60637

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Kayli Horne Chicago, IL 60615

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Kurt Witteman Chicago, IL 60605

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

---

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Louis Clark Chicago, IL 60637

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Matthew Raigosa Chicago, IL 60608

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. ### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

---

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Natalya Glaser Chicago, IL 60637

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Noah Hellermann New York, IL 11218

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Padgham Larson Galena, IL 61036

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Raj Kapoor Oak Park, IL 60302

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Rebekah Sugarman Syosset, IL 11791

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Rui Chicago, IL 60637

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. ### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

---

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Tim Law Chicago, IL 60637

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, Vincent Beltrano Chicago, IL 60615

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. Specifying the phase on which the threshold volume is based is necessary to prevent creative accounting. This issue is not merely academic - both gas and foam fracks are routinely used in the New Albany Shale (NAS) and in fact may be more successful and more widely used than waterbased fracturing due to the unique properties of the formation.<sup>1</sup> For example, a NAS well in Christian County, KY was stimulated with a gas fracture treatment using approximately 1 million standard cubic feet (scf) of nitrogen gas per stage for eight stages, for a total of approximately 8 million scf of nitrogen gas. Two wells in McLean County, KY were stimulated with mist fracture treatments composed of 92% to 99% nitrogen gas and 8% to 1 % water, using approximately 2 million scf of nitrogen gas per stage for nine stages, for a total of approximately 18 million scf of nitrogen gas per well. The proposed regulations provide no guidance as to how the 80,000 gallon/stage and 300,000 gallon

## Fair Economy Illinois

total thresholds should be applied to these gas-based fracturing jobs. The ramifications of this are disastrous, since it is possible to frack dolomite for oil using less than 300K base fluid, there is a strong financial inducement to do so since the excise tax then drops from +3% to 1/10 of 1% and the permit fee from \$13,500 to \$250. Furthermore according to Section 1-5 of the Act, "'Horizontal well' means a well with a wellbore drilled laterally at an angle of at least 80 degrees to the vertical." The Illinois Basin slopes upward as one moves north and west. Since toe up lateral wells will probably be common in shale gas nitrofracks (drainage problems in shallow, underpressurized wells), all that one may need to do is point the toe to the north, which is what geology dictates, and that well may be less than 80 degrees to the lateral. Even if the nitrogen issue is resolved we could still find a lot of gas fracks escaping regulations and frack taxes. Also, the phrase "fracturing fluid and proppant" may cause us problems because a 100% nitrofrack does not use proppant. Or, will the and conjunction be taken literally? Revisions needed: IDNR must come up with a scientifically sound method of determining thresholds for non-water fracks that is independently based on an evaluation of risk and field data. Otherwise, IDNR risks letting off the vast majority of wells from regulation altogether.

Sincerely, William Thomas Chicago, IL 60637

### Section 245.110 Definitions

The Department has not adequately specified how it will address those types of hydraulic fracturing operations in which water is not the base fluid or not the only base fluid – for example, fracturing operations using nitrogen or carbon dioxide (gas fracks) or fracturing that uses mixtures of gas and water (e.g. foam fracks, mist fracks). There are several issues that must be addressed. One issue is that the law defines the applicability threshold using gallons of base fluid. Gallons are unit of volume used to measure liquids. As such, it is not clear how the applicability threshold should be calculated for base fluids that are gases, or mixtures of gas and liquid. The situation is complicated by the fact that nitrogen used in fracturing is typically transported as a liquid but injected as a gas. The concern is that, if non-water base fluids are accounted for as liquid gallons, the gallonage total will fall below the applicability thresholds, even though the fracturing job is comparable in scale – and therefore risk – to a water-based frack in terms of chemical use, pressures, or other measures. We note, in this regard, that although the legislature provided no scientific support for the selection of the chosen threshold numbers and did not explain the origin of these numbers, we have surmised that the origin of the 80,000 gallons per stage and 300,000 gallons total thresholds are likely derived (albeit not entirely accurately in the case of the 80,000 gallons) from New York’s proposed regulations. However, New York derived these thresholds from a very limited analysis of volumes of base fluid used in water-based fracturing – not gas-based fracturing. Thus, the Department needs to come up with an appropriate means to express the threshold of applicability as it applies to non-water fracks. The key parameter for developing a comparable threshold should be identifying comparable risk. Addressing the problem by simply converting the water-based thresholds from gallons to cubic feet or another unit of volume appropriate to measure gases is not scientifically sound and does not sufficiently manage risk. A threshold derived in this way would be completely arbitrary and wholly divorced from the real environmental and health risks posed by such non-water fracks. Thresholds for gas-based fracks must be developed independently based on an evaluation of risk and field data from gas-based fracks. The rules must also specify whether the threshold volume for nitrogen, carbon dioxide, or other non-water base fluids applies to the liquid or gas phase of those fluids. For example: 1 million scf of nitrogen gas ~ 7,480,519 gallons of nitrogen gas ~ 10,739 gallons of liquid nitrogen. ### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Abby Dompke Chicago, IL 60607

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Alicia Klepfer Chicago, IL 60615

The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Bing Li Chicago, IL 60608

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Carolyn Treadway Normal, IL 61761

## Fair Economy Illinois

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, David Zask NY, IL 10128

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Eve Zuckerman Chicago, IL 60615

The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Jason Busser Dixon, IL 61021

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Kaitlon Busser Dixon, IL 61021

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Luke Dobbs Chicago, IL 60605

The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Matt Steffen Lake Zurich, IL 60047

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Nancy Freehafer Chicago, IL 60647

## Fair Economy Illinois

In reference to Subpart A: General Provisions

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

In reference to Subpart A: General Provisions

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Paulo Nacimiento Chicago, IL 60637

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Rebecca Quesnell Chicago, IL 60605

The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, sam zacher Chicago, IL 60637

## Fair Economy Illinois

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Sophia Johnson Chicago, IL 60605

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

### Section 245.110 Definitions

The rules unconstitutionally deprive many property owners of their property without notice and without compensation--thus, without due process of law. Under Illinois law, a person who owns the full bundle of rights in land owns the surface and all that is below it. So, when a landowner owns the full bundle of rights in the land, any drilling on, under, or without the landowner's consent is an illegal trespass and an unconstitutional taking. Similarly, any access to the surface without the landowner's consent is a trespass. The proposed rules would allow a trespass and a deprivation of property without due process of law, more specifically as follows: The rules not require a permit applicant to show that it has obtained the consent of the owners of the surface on which the vertical well will be drilled. The rules do not require a permit applicant to show that it has obtained the consent of the owners of the subsurface property through which the horizontal leg of the well will be drilled, nor even require notice to those property owners. In Section 245.110, DNR's proposed rules redefine real property rights in a manner inconsistent with current law. Specifically, the proposed rules would create an entirely new definition--"real property surface interest"--that is inconsistent with Illinois law in at least two respects. First, even when mineral rights are severed, the surface owner does not typically relinquish all rights in the subsurface. Second, the new definition narrows the intent of the law because the law uses the term "owner of real property" while the DNR's new definition excludes any property owner who owns the surface along with the subsurface and also excludes any property owner who owns the surface along with a controlling interest in the subsurface. Revisions Required: Delete the definition of "real property surface interest" in Section 245.110. Revise Section 245.210(A)(16)(A) & (B), on permit-application requirements, to require that the applicant show that it has obtained the consent of all the owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled. Revise Section 245.250(a)(1)(A), on public-notice requirements for permit applications, to require that permit applicants personally notify all owners of real property on which, under which, or through which the vertical and horizontal wells are to be drilled.

Sincerely, Young-In Chicago, IL 60637

### Section 245.110 Definitions

This comment relates to the definition of aquatic life in 245.110. This definition is too narrow. It does not include macro and micro invertebrates which often form the basis of the food chain for aquatic vertebrates like fish. Damage to invertebrate populations can reverberate throughout the aquatic ecosystem, so these species must also be protected in the regs. Oxygen and algae levels, as well as aquatic plant populations should also be included in the definition. In addition, it would be helpful if the regs specified the overall health of aquatic ecosystems in areas where fracking is taking place must be maintained by ongoing reviews of current indicators of quality of aquatic ecosystems.

### Section 245.110 Definitions

Tom Baker here, Chicago, and that this is even an issue suggests how public authority is pushed by private profit seeking interests who eschew the public interests for health and well-being. IDNR, with responsibility first to the public, people, the families, the children, with responsibility to regulate and guide conduct and operations of utilities must not permit "fracking", period. Numerous studies and testimony from people experiencing the consequences of fracking should be testimony enough. And, no, the industry has not engineered a way for this ridiculous procedure to be safe. Why is it even considered We would find it encouraging should the IDNR compel development of alternative methods. Fracking, NO Study and development of alternatives, YES.

Sincerely, Thomas Baker Chicago, IL 60626

### Section 245.110 Definitions

Trade Secret Disclosure to Health Professionals Relevant parts of the Proposed Administrative Rules: Subpart G: Chemical Disclosure; Trade Secrets (245.700-245.730) 245.730 Trade Secret Disclosure to Health Professional The proposed language concerning disclosure of trade secret-protected information to health professionals is neither consistent with the statute nor protective of the public. Right to Know. Section 1-77(l) of the Act is clear that information shall be provided, as needed, to health professionals who demonstrate a need for it. Yet, section 245.730 of the Rules diminishes the language of the Act, stating only that the Department "may" provide information to health professionals who demonstrate a need for it. Limitation to "normal business hours." Subsection 245.730(b)(1) of the Rules states, in the event of an emergency, that a health professional may call the Department during "normal business hours." For an emergency that occurs after hours, the Rules suggest calling the trade secret holder. This is inadequate. The Department should provide a 24-hour hotline for emergency calls pursuant to this section. "Trade Secret Holder." Subsection 245.730(b)(2) of the Rules allows a health professional to seek the necessary information from a "trade secret holder," but there is no means provided for the health professional to know who the trade secret holder is, or what phone number to use to reach it. Furthermore, this provision is found nowhere in the statute, seemingly adding another unnecessary burden on the health professional. Lack of a time limit for the Department's response. The Department should abide by the same 3-hour time limit for a response that applies to trade secret holders pursuant to 245.730(b)(2).

Sincerely, Sandra Nickerson West Dundee, IL 60118

This comment is in reference to Page 3, Paragraph 6 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, which states: "Published studies or reports, and sources of underlying data, used to compose this rulemaking: None". Simply put, the State of Illinois cannot have sound regulation without good data. There is significant need for further study of horizontal hydraulic fracturing technology prior to its use in the State of Illinois. If the technology was as safe as the industry is claiming, why do there continue to be so many accidents and violations in states where fracking is already occurring? Suggested resources include the twenty-four (24) pages of "References" included in U.S. EPA's December 2012 Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources. See: U.S. EPA: Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources: Progress Report, (EPA 601/R-12/011 December 2012), available at:<http://www.epa.gov/hfstudy>.

In reference to Subpart A: General Provisions (245.100-245.120)

This comment is in reference to Page 3, Paragraph 6 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, which states: "Published studies or reports, and sources of underlying data, used to compose this rulemaking: None". Simply put, the State of Illinois cannot have sound regulation without good data. There is significant need for further study of horizontal hydraulic fracturing technology prior to its use in the State of Illinois. If the technology was as safe as the industry is claiming, why do there continue to be so many accidents and violations in states where fracking is already occurring? Suggested resources include the twenty-four (24) pages of "References" included in U.S. EPA's December 2012 Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources. See: U.S. EPA: Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources: Progress Report, (EPA 601/R-12/011 December 2012), available at:<http://www.epa.gov/hfstudy>.

In reference to Subpart A: General Provisions (245.100-245.120)

This comment is in reference to Page 3, Paragraph 6 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, which states: "Published studies or reports, and sources of underlying data, used to compose this rulemaking: None". Simply put, the State of Illinois cannot have sound regulation without good data. There is significant need for further study of horizontal hydraulic fracturing technology prior to its use in the State of Illinois. If the technology was as safe as the industry is claiming, why do there continue to be so many accidents and violations in states where fracking is already occurring? Suggested resources include the twenty-four (24) pages of "References" included in U.S. EPA's December 2012 Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources. See: U.S. EPA: Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources: Progress Report, (EPA 601/R-12/011 December 2012), available at:<http://www.epa.gov/hfstudy>.

In reference to Subpart A: General Provisions (245.100-245.120)

This comment is in reference to Page 3, Paragraph 6 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, which states: "Published studies or reports, and sources of underlying data, used to compose this rulemaking: None". Simply put, the State of Illinois cannot have sound regulation without good data. There is significant need for further study of horizontal hydraulic fracturing technology prior to its use in the State of Illinois. If the technology was as safe as the industry is claiming, why do there continue to be so many accidents and violations in states where fracking is already occurring? Suggested resources include the twenty-four (24) pages of "References" included in U.S. EPA's December 2012 Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources. See: U.S. EPA: Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources: Progress Report, (EPA 601/R-12/011 December 2012), available at:<http://www.epa.gov/hfstudy>.

Sincerely, Jady YTolda chicago, IL 60637

Simply put, the State of Illinois cannot have sound regulation without good data. There is significant need for further study of horizontal hydraulic fracturing technology prior to its use in the State of Illinois. If the technology was as safe as the industry is claiming, why do there continue to be so many accidents and violations in states where fracking is already occurring? Suggested resources include the twenty-four (24) pages of "References" included in U.S. EPA's December 2012 Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources. See: U.S. EPA: Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources: Progress Report, (EPA 601/R-12/011 December 2012), available at:<http://www.epa.gov/hfstudy>.

Sincerely, Lauren San Juan Chicago, IL 60608

In reference to Subpart A: General Provisions (245.100-245.120)

This comment is in reference to Page 3, Paragraph 6 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, which states: "Published studies or reports, and sources of underlying data, used to compose this rulemaking: None". Simply put, the State of Illinois cannot have sound regulation without good data. There is significant need for further study of horizontal hydraulic fracturing technology prior to its use in the State of Illinois. If the technology was as safe as the industry is claiming, why do there continue to be so many accidents and violations in states where fracking is already occurring? Suggested resources include the twenty-four (24) pages of "References" included in U.S. EPA's December 2012 Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources. See: U.S. EPA: Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources: Progress Report, (EPA 601/R-12/011 December 2012), available at:<http://www.epa.gov/hfstudy>.

In reference to Subpart A: General Provisions (245.100-245.120)

This comment is in reference to Page 3, Paragraph 6 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, which states: "Published studies or reports, and sources of underlying data, used to compose this rulemaking: None". Simply put, the State of Illinois cannot have sound regulation without good data. There is significant need for further study of horizontal hydraulic fracturing technology prior to its use in the State of Illinois. If the technology was as safe as the industry is claiming, why do there continue to be so many accidents and violations in states where fracking is already occurring? Suggested resources include the twenty-four (24) pages of "References" included in U.S. EPA's December 2012 Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources. See: U.S. EPA: Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources: Progress Report, (EPA 601/R-12/011 December 2012), available at:<http://www.epa.gov/hfstudy>.

In reference to Subpart A: General Provisions (245.100-245.120)

This comment is in reference to Page 3, Paragraph 6 of the Proposed Hydraulic Fracturing Regulatory Act administrative rules, which states: "Published studies or reports, and sources of underlying data, used to compose this rulemaking: None". Simply put, the State of Illinois cannot have sound regulation without good data. There is significant need for further study of horizontal hydraulic fracturing technology prior to its use in the State of Illinois. If the technology was as safe as the industry is claiming, why do there continue to be so many accidents and violations in states where fracking is already occurring? Suggested resources include the twenty-four (24) pages of "References" included in U.S. EPA's December 2012 Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources. See: U.S. EPA: Study of the Potential Impacts of Hydraulic Fracturing on Drinking Water Resources: Progress Report, (EPA 601/R-12/011 December 2012), available at:<http://www.epa.gov/hfstudy>.

Sincerely, Tori Root Naperville, IL 60564

In reference to Subpart A: General Provisions (245.100-245.120)

According to section 5-40 of the Illinois Administrative Procedure Act, At least one agency representative shall be present during the hearing who is qualified to respond to general questions from the public regarding the agency's proposal and the rulemaking process. 5 ILCS 100/5-40. However, even though IDNR representatives were present, it was made clear by the hearing officer at each of the public hearings in Chicago, Ina, Effingham, Decatur, and Carbondale that the panel members would, in fact, not answer questions. In a number of instances, such as the hearing that I attended in Chicago, the hearing officer stated that IDNR representatives would simply listen and would not respond to comments, concluding that the hearing was not a question-and-answer session. Agency officials are required by the Illinois Administrative Procedure Act to answer general questions regarding the proposed rules and the rule making process. However because not one agency representative responded to public questions at any of these hearings, these public hearings were held in violation of the Act. To rectify this violation, IDNR should either hold additional hearings in Chicago, Ina, Effingham, Decatur and Carbondale or issue a new First Notice, initiating a new round of new public hearings with a new public comment period.

Sincerely, Sara Buck Chicago , IL 60640

In reference to Subpart A: General Provisions (245.100-245.120)

Allowing fracking in the Wabash Valley and New Madrid earthquake zones is deplorable. The New Madrid is a major fault line, causing earthquakes of over 7 on the Richter magnitude scale. Not only is increased seismic activity from wastewater wells a concern, but also the damage to the general public and environment. Furthermore, fracking in the 100-year floodplain zone is another environmental disaster waiting to happen. Recall the increase in seismic activity in Tulsa, OK since fracking began in 2009; or in Youngstown, OH, which never experienced an earthquake according to research dating back to 1776, but experienced 109 quakes in 2011 presumably due to fracking wastewater being pumped deep underground; or in North Texas, which was hit with a string of 16 earthquakes in November of 2013, and according to earthquake researcher at the University of Texas, Cliff Frolich, I'd say it certainly looks very possible that the earthquakes are related to injection wells. The truth is undeniable, fracking leads to increased seismic activity. In conclusion, there should be no drilling in our floodplains or seismic zones because it will only lead to widespread devastation.

Sincerely, Ashley Williams Ottawa, IL 61350

---

In reference to Subpart A: General Provisions (245.100-245.120)

Although it may seem that Illinois has an abundance of clean drinking water, I am concerned about the pollution related to fracking. If we pollute our drinking water, we will not survive. Please make the regulations more stringent to protect all of us, not just those who want to drill for natural gas.

Sincerely, Emily Lorenz Chicago, IL 60626

## Fair Economy Illinois

---

In reference to Subpart A: General Provisions (245.100-245.120)

An earlier comment quoted OSHA data that suggested that oil and gas drilling workers are 7 times higher than workers from other occupations to die on the job. But even more recent data from the Bureau of Labor statistics suggests that [i]n fact, the fatality rate among oil and gas workers is now nearly eight times higher than the all-industry rate of 3.2 deaths for every 100,000 workers, the highest level since the government started compiling the data in 2003. The article also quotes a NIOSH representative from the CDC, who says that there are numerous reasons for the upsurge in deaths in this sector, including binge-hiring in newly developing industry sectors like hydraulic fracturing, 12-14 hour shifts worked for one to two consecutive weeks, and lack of experience/inadequate training. ([http://www.npr.org/2013/12/27/250807226/on-the-job-deaths-spiking-as-oil-drillingquickly-expands?ft=1&f=2&utm\\_source=feedburner&utm\\_medium=feed&utm\\_campaign=Feed%3A+NprProgramsATC+%28NPR+Programs%3A+All+Things+Considered%29&utm\\_content=Yahoo+Search+Results](http://www.npr.org/2013/12/27/250807226/on-the-job-deaths-spiking-as-oil-drillingquickly-expands?ft=1&f=2&utm_source=feedburner&utm_medium=feed&utm_campaign=Feed%3A+NprProgramsATC+%28NPR+Programs%3A+All+Things+Considered%29&utm_content=Yahoo+Search+Results)) IDNR absolutely must enforce OSHA standards, particularly regarding dust and radioactivity. IDNR must also develop and enforce rules that address inherently dangerous workplace conditions, shift-lengths, and transport of material to and from operations-- among many other workplace issues cited in the literature.

Sincerely, Sara Buck Chicago , IL 60640

In reference to Subpart A: General Provisions (245.100-245.120)

As a student organizer working to avert catastrophic climate change, and am extremely concerned about the IDNR's proposed rules on fracking. There are a plethora of holes in these regulations. For instance, It is irresponsible for planners of the state to consider allowing fracking in areas that are prone to tornadoes, without creating adequate rules that will protect citizens from the toxic flow back water. It is not safe to allow gas companies to frack in Illinois. Not only are these companies destroying fresh, drinking water in a world that continues to lack access to drinking water, but they haven't even established proper means to ensure that this toxic flow back water is stored properly to prevent contamination. The possibilities of this toxic water being out in the open in a land prone to tornadoes - where debris from tornadoes are found over 150 miles from where the tornado is - are disastrous and dangerous to all Illinois residents. I urge you to please reconsider allowing fracking in our state. It is unsafe and dangerous to our health and environment.

Sincerely, Dylan Amlin 4750 N Sheridan Chicago, IL 606040

In reference to Subpart A: General Provisions (245.100-245.120)

As a wife, I worry everyday when my husband goes to work at a steel plant. There are many dangers and chemicals and often some really long hours that he works. I have first hand experience getting a call after he was injured on the job site due to failure of others to follow protocol. It is a call and experience NOBODY should have to experience. We have the opportunity before things begin to take as many precautionary measures as possible. Problems: The fatality rate of gas and oilfield workers is 7.6 times above all other industries and set an all-time high record in 2012 (King 2013). An inescapably dangerous work setting under the best of circumstances, frack pads are rendered even more dangerous by well operators who eschew workplace safety standards and who force employees to work excessively and dangerously long hours. Sixteen (16) to 20 hour work shifts can be scheduled with the end result that exhausted workers make mistakes in an unforgiving environment or fall asleep behind the wheel of a vehicle, often claiming their own lives and the lives of residents who happen to be on the wrong road at the wrong time (Urbina 2012). There are at least two work related dangers at frack pads that should fall under OSHA regulations: exposure to (1) radiation and (2) silica dust. Both can increase rates of cancer among exposed workers and both kinds of work-site related exposure are limited and regulated by OSHA. Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Sincerely, Kathryn Chapman Hamburg, IL 62045

In reference to Subpart A: General Provisions (245.100-245.120)

Days after the devastating tornadoes that hit on Sunday, 11/17/13, people from over 150 miles away were taking part in an online social media effort to return personal items to the affected families. Fracking sites are just as vulnerable to storm damage which is VERY common here in Illinois (including in off months such as January when storms hit northern Illinois a few years ago). In order to keep the people of Illinois safe should sites be hit by a storm we need to think ahead and require as many safety measures as possible be put into place. You can not undo a deed once done and we have the chance NOW to make sure that fracking does not move forward without proper precautions put into place.

Sincerely, Kathryn Chapman RR 2 Box 20 Hamburg, IL 62045

In reference to Subpart A: General Provisions (245.100-245.120)

Dear IDNR, Section 1-53 of the regulatory bill requires that fracking operations be conducted in a “manner that will protect the public health and safety and prevent pollution.” But this is in direct opposition to the large scale environmental disasters which can be a result of fracking. The New Madrid Earthquake zone has been known to historically cause “major” earthquakes of over 7 on the Richter magnitude scale. The Illinois Emergency Management Agency itself identifies these areas with its most severe earthquake zone ratings of “DESTRUCTIVE” and “RUINOUS.” An earthquake of these magnitudes, compounded with fracking and injection wells spread throughout the affected zone is quite literally, a recipe for disaster. Earthquakes of these magnitudes can easily damage fracking wells causing TOXIC and RADIOACTIVE fracking fluids to pour into the ground and contaminate soil and water for hundreds of thousands of Illinoisans. Even Ohio Governor, John Kasich, a fracking advocate, has issued an executive order requiring operators to conduct seismic studies before the state will issue well permits. The environmental devastation caused by the recent floods in Colorado is a case in point. Inundated oil pads, flooded wells, overturned tanks, and ruptured lines were just a few of problems experienced in Colorado as a result of wide-scale flooding. A damaged oil tank dumped 5,250 gallons of oil into the South Platte River south of Milliken, Colorado on 9/18/13 during the flood. You must avoid fracking in active seismic zones and flood plains, for if it is allowed fracking wastewater can spill out of the pit and into floodwaters exposing every living thing downstream to the chemicals, brine, radioactivity, etc. that was in the fracking pit.

Sincerely, Kurt Witteman 425 S Wabash Ave WBRH 41 Chicago, IL 60605

In reference to Subpart A: General Provisions (245.100-245.120)

Dear IDNR, Section 1-53 of the regulatory bill requires that fracking operations be conducted in a “manner that will protect the public health and safety and prevent pollution.” But this is in direct opposition to the large scale environmental disasters which can be a result of fracking. The New Madrid Earthquake zone has been known to historically cause “major” earthquakes of over 7 on the Richter magnitude scale. The Illinois Emergency Management Agency itself identifies these areas with its most severe earthquake zone ratings of “DESTRUCTIVE” and “RUINOUS.” An earthquake of these magnitudes, compounded with fracking and injection wells spread throughout the affected zone is quite literally, a recipe for disaster. Earthquakes of these magnitudes can easily damage fracking wells causing TOXIC and RADIOACTIVE fracking fluids to pour into the ground and contaminate soil and water for hundreds of thousands of Illinoisans. Even Ohio Governor, John Kasich, a fracking advocate, has issued an executive order requiring operators to conduct seismic studies before the state will issue well permits. The environmental devastation caused by the recent floods in Colorado is a case in point. Inundated oil pads, flooded wells, overturned tanks, and ruptured lines were just a few of problems experienced in Colorado as a result of wide-scale flooding. A damaged oil tank dumped 5,250 gallons of oil into the South Platte River south of Milliken, Colorado on 9/18/13 during the flood. You must avoid fracking in active seismic zones and flood plains, for if it is allowed fracking wastewater can spill out of the pit and into floodwaters exposing every living thing downstream to the chemicals, brine, radioactivity, etc. that was in the fracking pit.

Sincerely, Shawn Mukherji 491 Vaughn Cir Aurora, IL 60502

In reference to Subpart A: General Provisions (245.100-245.120)

Dear IDNR, This comment is in response to the paragraphs of the published notices setting the dates for the public hearings on the Proposed Amendments to the Rules under the Oil and Gas Act and on the Proposed Rules under the Hydraulic Fracturing Regulatory Act. 37 Illinois Register 18081, 18081-82 (November 15, 2013); 37 Illinois Register 18097, 18099 (November 15, 2013); 37 Illinois Register 19746 (December 6, 2013); 37 Illinois Register 19747 (December 6, 2013). DNR did not provide the required public notice for any of the public hearings, because in each case the notice for the hearing was not published in the Illinois Register at least 20 days before the hearing. Although the Illinois Administrative Procedure Act allows DNR to hold a public hearing, in response to a request for a hearing, less than 20 days after public notice in the Illinois Register if the notice of hearing is published in the notice of proposed rulemaking (5 ILCS 100/5-40), DNR has chosen by rule to require a minimum of 20 days' notice. DNR's adopted rule for scheduling public hearings states as follows: The Hearing Officer shall set a time and place for hearing and shall give notice as follows, at least 20 days prior to the date of the hearing; a) to the proponent, by mail; b) to members of the general public, by means of a general news release and notice in the Illinois Register. 2 Ill. Admin. Code 825.140. The first notice of public hearings--for Chicago and Ina--was published in the Illinois Register on November 15, 2013. But the Chicago hearing took place on November 26, 2013, and the Ina hearing took place on December 3, 2013. Each of those hearings was held on less than 20 days' notice. The second notice of public hearings--for Effingham, Decatur, and Carbondale--was published in the Illinois Register on December 6, 2013. But the Effingham hearing took place on December 16, 2013, the Decatur hearing took place on December 17, 2013, and the Carbondale hearing took place on December 19, 2013. Each of those hearings was held on less than 20 days' notice. Thus, DNR's public hearings were held in violation of its own administrative rules. These violations deprived the citizens of a meaningful opportunity to be heard. The remedy for this violation is either additional hearings in these areas, each with the required minimum 20 days' notice, or alternatively, a new First Notice with the opportunity for new public hearings and a new public comment period. Kurt

In reference to Subpart A: General Provisions (245.100-245.120)

Dialogue and the democratic process are extremely important to me. Having deployed to Iraq as a member of the Army, it is baffling to return home and see examples of the voice of American citizens is being undermined and even silenced during basic democratic processes such as public hearings. This comment concerns the public hearings held by DNR on the Proposed Amendments to the Rules under the Oil and Gas Act and on the Proposed Rules under the Hydraulic Fracturing Regulatory Act. 37 Illinois Register 18081, 18081-82 (November 15, 2013); 37 Illinois Register 18097, 18099 (November 15, 2013); 37 Illinois Register 19746 (December 6, 2013); 37 Illinois Register 19747 (December 6, 2013). Comment: Section 5-40 of the Illinois Administrative Procedure Act provides as follows: At least one agency representative shall be present during the hearing who is qualified to respond to general questions from the public regarding the agency's proposal and the rulemaking process. 5 ILCS 100/5-40. At the public hearings in Chicago, (11/26/13), Ina (12/3/13), Effingham (12/16/13), Decatur (12/17/13) and Carbondale (12/19/13), DNR representatives were present on the panel, along with the hearing officer. However, at each of the hearings, the hearing officer made various statements that informed the citizens in attendance that the panel members would NOT answer questions. For example, the hearing officer stated that the DNR representatives were there to listen, that they would not respond to any comments, and that the hearing was not a question-and-answer session. Thus, because the agency officials were not available to answer general questions regarding the proposal and the rulemaking process, these public hearings were held in violation of the Illinois Administrative Procedure Act. The remedy for these violations is either additional hearings in Chicago, Ina, Effingham, Decatur and Carbondale or, alternatively, a new First Notice with the opportunity for new public hearings and a new public comment period.

Sincerely, Bing Li Chicago, IL 60608

In reference to Subpart A: General Provisions (245.100-245.120)

Even if the Illinois Department of Natural Resources was allowed to regulate industry rather than allow it to continue with business as usual, the IDNR barely has enough funding to manage State Parks. Surface water in lakes, rivers, and streams is already at risk from agricultural run-off and municipal sewage systems. Reversing the Chicago River has contributed to a larger Dead Zone in the Gulf than anything created by the BP spill. Do not put aquifers at risk! Reconsider the regulations put forth and stop fracking in Illinois now to protect our air, water, and climate.

Sincerely, Robert Kolkebeck Park Forest, IL 60466

In reference to Subpart A: General Provisions (245.100-245.120)

Failure to address workplace rules or worker safety. How does this affect me: Health and well-being  
Relevant parts of the Proposed Administrative Rules: Subpart A: General Provisions (245.100-245.120)  
Problems: The fatality rate of gas and oilfield workers is 7.6 times above all other industries and set an all-time high record in 2012 (King 2013). An inescapably dangerous work setting under the best of circumstances, frack pads are rendered even more dangerous by well operators who eschew workplace safety standards and who force employees to work excessively and dangerously long hours. Sixteen (16) to 20 hour work shifts can be scheduled with the end result that exhausted workers make mistakes in an unforgiving environment or fall asleep behind the wheel of a vehicle, often claiming their own lives and the lives of residents who happen to be on the wrong road at the wrong time (Urbina 2012). There are at least two work related dangers at frack pads that should fall under OSHA regulations: exposure to (1) radiation and (2) silica dust. Both can increase rates of cancer among exposed workers and both kinds of work-site related exposure are limited and regulated by OSHA. Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Sincerely, Janet McDonnell 1322 North Vail Avenue Arlington Heights, IL 60004

In reference to Subpart A: General Provisions (245.100-245.120)

I have heard for years that in at least one of the geologically recent earthquakes in the New Madrid fault the shaking was severe and widespread enough that bells in churches on the East Coast rang by themselves. The only reason there was not severe disaster in St. Louis and across Illinois was that most buildings at that time were one story, perhaps two, and there were relatively few of them. Those things have changed since the early-to-mid 1800's. St. Louis, Champaign-Urbana, Springfield--how would they fare now in a 7-7.5 earthquake in their vicinity? Then add to that catastrophe thousands of gallons of unknown but toxic chemicals, radioactive minerals brought up from underground and also of unknown composition, released from open-air pits or storage tanks by the earthquake, flooding out over the area, contaminating everything and everyone. And the icing on the cake is that the fracking activity--fracturing rocks deep underground--could easily trigger such earthquakes, that otherwise might have happened a thousand years in the future. Until the gas industry has a better method of wastewater disposal than open-air pits, NO fracking should be allowed. They are using toxic volatile organic compounds by the ton, and then letting them evaporate into our air. These include benzene, a known carcinogen that was considered so dangerous that if we wanted to buy it for our lab at Argonne National Laboratory, we needed to fill out a special form justifying the purchase--for amounts in the teaspoon-to-teacup range! But frackers can force it into the earth (and our drinking-water) BY THE TANKER-TRUCKLOAD!!! WITHOUT EVEN TELLING ANYONE--let alone getting permission!!! AND THEN, THE PART THAT COMES BACK OUT IN THE WASTEWATER IS PUT IN OPEN PITS TO POLLUTE THE AIR we all breathe!!! If a teacupful of benzene can give five people cancer, how many people can get cancer from breathing a tanker-truckload? Then there is the enormous water usage. How many years will it take them to drain Lake Michigan? Many industries use a lot of water, and have to clean it up before they can release it back to the rivers and streams it came from. But there is NO WAY to clean up the unholy mix of 600 chemicals that have been identified in fracking wastewater! It is indeed wasted--removed from the water cycle permanently (or at least until an accident releases it from those open pits to contaminate everything it touches for miles around and downstream, all the way to the Gulf of Mexico and in the Gulf itself.) In short, fracking is a total environmental disaster for which we will be paying the price for hundreds of years, and then, because they are getting so much natural gas that we would be able to buy it for almost nothing on an open market, they decide that they will liquify it (a very energy-intensive process) and ship it overseas. Thus, we get all the environmental degradation, cancer cases, droughts and other negatives, while they sell us our gas at prices kept artificially high by shipping our gas overseas for the greater profits of the companies that are poisoning us! What is wrong with this picture? EVERYTHING!!! All fracking should be banned!

Sincerely, Elizabeth A. Cerny 7728 Williams St. Downers Grove, IL 60516

In reference to Subpart A: General Provisions (245.100-245.120)

I was disappointed to learn that the fracking rules suggested by the Illinois DNR were much weaker than they should be in light of the legislation that had passed. That legislation was already a compromise that failed to adequately protect the local communities and their environments in areas being leased for fracking. Frankly, it was the DNR's responsibility to ensure that companies wishing to frack in Illinois would be held to a high but reasonable standard. Business as usual is unacceptable. I have seen the documentary Gasland, which exposes how ruthlessly such oil and natural gas deposits can be developed. The companies involved care only about their profits and not at all about the place where they are operating. There is also the issue of the huge drain on water resources and the ugly and damaging mining of sandstone deposits. I am in favor of a moratorium on fracking but, short of that, I demand rigorous regulation. Remember, too, that continued use of carbon-based fuels is moving us along on the climate change curve in a way that demands a response!

Sincerely, Mary Warren Wheaton, IL 60187

In reference to Subpart A: General Provisions (245.100-245.120)

I was disappointed to learn that the fracking rules suggested by the Illinois DNR were much weaker than they should be in light of the legislation that had passed. That legislation was already a compromise that failed to adequately protect the local communities and their environments in areas being leased for fracking. Frankly, it was the DNR's responsibility to ensure that companies wishing to frack in Illinois would be held to a high but reasonable standard. Business as usual is unacceptable. I have seen the documentary Gasland, which exposes how ruthlessly such oil and natural gas deposits can be developed. The companies involved care only about their profits and not at all about the place where they are operating. There is also the issue of the huge drain on water resources and the ugly and damaging mining of sandstone deposits. I am in favor of a moratorium on fracking but, short of that, I demand rigorous regulation. Remember, too, that continued use of carbon-based fuels is moving us along on the climate change curve in a way that demands a response!

In reference to Subpart A: General Provisions (245.100-245.120)

It doesn't really matter how much cheap domestic energy you get if you end up contaminating people's drinking water in the process. It doesn't really matter that natural gas has 50% fewer CO2 emissions if you don't take the proper regulatory steps to limit methane emissions. So, we're just going to disregard people's health and safety and disregard our climate and environment all for what? For more natural gas that will only serve as a stopgap between the oil age and the clean energy that follows so we can cling to the fossil fuel age for a bit longer? It doesn't really make any sense to me.

Sincerely, David Dickey Evergreen Park, IL 60805

In reference to Subpart A: General Provisions (245.100-245.120)

It is irresponsible for planners of the state to consider allowing fracking in areas that are prone to tornadoes, without creating adequate rules that will protect citizens from the toxic flow back water. It is not safe to allow gas companies to frack in Illinois. Not only are these companies destroying fresh, drinking water in a world that continues to lack access to drinking water, but they haven't even established proper means to ensure that this toxic flow back water is stored properly to prevent contaminations. The possibilities of this toxic water being out in the open in a land prone to tornadoes - where debris from tornadoes are found over 150 miles from where the tornado is - are disastrous and dangerous to all Illinois residents. I urge you to please reconsider allowing fracking in our state. It is unsafe and dangerous to our health and environment.

Sincerely, Virginia Baker 2007 S BLUE ISLAND AVE APT 3F CHICAGO, IL 606082928

In reference to Subpart A: General Provisions (245.100-245.120)

Let me remind IDNR of an important article released this summer by William L. Ellsworth of the Earthquake Science Center, U.S. Geological Survey, Menlo Park, CA 94025, USA. E-mail: [ellsworth@usgs.gov](mailto:ellsworth@usgs.gov) (for your convenience). Source: Science 12 July 2013: Vol. 341 no. 6142 DOI: 10.1126/science.1225942 Link: <http://www.sciencemag.org.proxy.cc.uic.edu/content/341/6142/1225942.full> The title? Injection-Induced Earthquakes. Ellsworth notes: [E]arthquakes can be induced by either reducing the effective normal stress or raising the shear stress (3–5). It has been known for decades that large reservoirs can induce earthquakes either from the effect of the elastic load of the reservoir or by diffusion of elevated pore pressure (34). Well-known examples include the deadly 1967 M 6.3 earthquake in Koyna, India (35). . . . [D]eep reservoirs in tectonically active zones carry a real risk of inducing damaging earthquakes. Earthquakes throughout the world are also recognized to be associated with mining, petroleum and gas production, and geothermal energy extraction. Withdrawal of large volumes of fluid or gas from a reservoir or creation of a void space in a mine may modify the state of stress sufficiently to induce earthquakes that relax the stress perturbations (4). Production may also release tectonic stress. The long-term pumping of groundwater may have induced the deadly Mw 5.1 earthquake in Lorca, Spain, on 11 May 2011 (38). Porepressure changes alone can also induce seismicity, such as by waterflooding for secondary recovery of oil or to maintain the fluid level in a geothermal reservoir, or when a mine is abandoned and allowed to flood (3, 4). He notes that currently injection-induced earthquakes have not caused serious fatalities due to strong building codes—even though earthquakes of similar size have wrecked havoc in other countries. However, he also notes that we don't know enough to predict how hydraulic fracturing will affect seismic activity over the long term. And as the Mother Jones article notes below, homes are destroyed and families struggle to return to normalcy after such quakes. Does IDNR want to be responsible for the loss of property, livelihood, and life? Take Oklahoma, a previously largely earthquake-free zone, which has had multiple recordbreaking earthquakes over the last year or so. Many scientists are suggesting that fracking caused the quakes. Case in point: <http://news.nationalgeographic.com/news/energy/2013/03/130329-wastewater-injection-likely-caused-quake/> <http://www.motherjones.com/environment/2013/03/does-fracking-cause-earthquakes-wastewaterdewatering> [http://www.huffingtonpost.com/2013/10/24/okla-earthquake-swarm-fracking\\_n\\_4158134.html](http://www.huffingtonpost.com/2013/10/24/okla-earthquake-swarm-fracking_n_4158134.html) In this last article, the author states: From 1975 to 2008, central Oklahoma experienced an average of one to three magnitude 3.0 earthquakes or larger. Since 2008, that average has increased to around 40 per year, according to data collected by the U.S. Geological Survey. Clearly, we are still learning about the effects of hydraulic fracturing, but we do know that it can cause earthquakes, even significant earthquakes, in places where there was no significant seismic activity. Hydraulic fracturing thus should not be permitted in areas with active seismic zones, such as the New Madrid Earthquake zone, which has been known to historically cause “major” earthquakes of over 7 on the Richter magnitude scale. The Illinois Emergency Management Agency labels these areas with the most severe earthquake zone ratings, “Destructive” and “Ruinous.” Placing fracking operations within an

## Fair Economy Illinois

---

active seismic zone at this point in time seems suicidal. In addition, hydraulic fracturing operations should not operate within the 100-year floodplain, where open-air pits are particularly vulnerable, potentially exposing all life to the contaminants in the wastewater.

Sincerely, Sara Buck Chicago , IL 60640

In reference to Subpart A: General Provisions (245.100-245.120)

Many countries around the world have outlawed hydraulic fracturing, and many more are carefully considering how to study and regulate these new practices, since they have been demonstrated to pollute water. Why should Illinois residents be held to lesser standards? The rewards may seem attractive, but the risks to health, industry, and agriculture are too great. Please reconsider the regulations put forth and stop fracking in Illinois now to protect our air, water, and climate.

Sincerely, Ben Heymer Chicago, IL 60647

In reference to Subpart A: General Provisions (245.100-245.120)

Number of draft regulations proposed by Illinois Dept. of Natural Resources describing safety measures regarding tornado strikes on fracking sites: ZERO. Number of tornadoes in Illinois in the last 10 years: 674. Historically, the number and intensity of tornadoes in Illinois is very high. "In fact, Illinois has experienced some of the worst tornadoes in US history." Dr. Jim Angel, Illinois State Climatologist. Every county in Illinois has had multiple tornadoes as demonstrated by the maps in the following links:  
<http://www.isws.illinois.edu/atmos/statecli/tornado/ilmaps.htm>  
[http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC\\_Tornado...](http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC_Tornado...) A big swath of Washington, IL was flattened by a tornado on Sunday, 11/17/13. What would have happened if this tornado had hit an area of the state covered in fracking sites? Debris from the tornado has been found over 150 miles away. Imagine if that debris had included "temporarily" stored flowback water or tanks filled with frack fluid or produced water!

Sincerely, , IL

Number of tornadoes in Illinois in the last 10 years: 674. Historically, the number and intensity of tornadoes in Illinois is very high. "In fact, Illinois has experienced some of the worst tornadoes in US history." Dr. Jim Angel, Illinois State Climatologist. Every county in Illinois has had multiple tornadoes as demonstrated by the maps in the following links:  
<http://www.isws.illinois.edu/atmos/statecli/tornado/ilmaps.htm>  
[http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC\\_Tornado...](http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC_Tornado...) A big swath of Washington, IL was flattened by a tornado on Sunday, 11/17/13. What would have happened if this tornado had hit an area of the state covered in fracking sites? Debris from the tornado has been found over 150 miles away. Imagine if that debris had included "temporarily" stored flowback water or tanks filled with frack fluid or produced water!

Sincerely, Amelia Dmouska Chciago, IL 60637

[http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC\\_Tornado...](http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC_Tornado...) A big swath of Washington, IL was flattened by a tornado on Sunday, 11/17/13. What would have happened if this tornado had hit an area of the state covered in fracking sites? Debris from the tornado has been found over 150 miles away. Imagine if that debris had included "temporarily" stored flowback water or tanks filled with frack fluid or produced water!

Sincerely, Bruce Ostdick Elgin, IL 60123

In reference to Subpart A: General Provisions (245.100-245.120)

Number of draft regulations proposed by Illinois Dept. of Natural Resources describing safety measures regarding tornado strikes on fracking sites: ZERO. Number of tornadoes in Illinois in the last 10 years: 674. Historically, the number and intensity of tornadoes in Illinois is very high. "In fact, Illinois has experienced some of the worst tornadoes in US history." Dr. Jim Angel, Illinois State Climatologist. Every county in Illinois has had multiple tornadoes as demonstrated by the maps in the following links:  
<http://www.isws.illinois.edu/atmos/statecli/tornado/ilmaps.htm>  
[http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC\\_Tornado...](http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC_Tornado...) A big swath of Washington, IL was flattened by a tornado on Sunday, 11/17/13. What would have happened if this tornado had hit an area of the state covered in fracking sites? Debris from the tornado has been found over 150 miles away. Imagine if that debris had included "temporarily" stored flowback water or tanks filled with frack fluid or produced water!

Sincerely, Gianna Chacon Chicago, IL 60605

[http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC\\_Tornado...](http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC_Tornado...) A big swath of Washington, IL was flattened by a tornado on Sunday, 11/17/13. What would have happened if this tornado had hit an area of the state covered in fracking sites? Debris from the tornado has been found over 150 miles away. Imagine if that debris had included "temporarily" stored flowback water or tanks filled with frack fluid or produced water!

Sincerely, jd paulus wheaton, IL 60187

In reference to Subpart A: General Provisions (245.100-245.120)

Number of draft regulations proposed by Illinois Dept. of Natural Resources describing safety measures regarding tornado strikes on fracking sites: ZERO. Number of tornadoes in Illinois in the last 10 years: 674. Historically, the number and intensity of tornadoes in Illinois is very high. "In fact, Illinois has experienced some of the worst tornadoes in US history." Dr. Jim Angel, Illinois State Climatologist. Every county in Illinois has had multiple tornadoes as demonstrated by the maps in the following links:  
<http://www.isws.illinois.edu/atmos/statecli/tornado/ilmaps.htm>  
[http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC\\_Tornado...](http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC_Tornado...) A big swath of Washington, IL was flattened by a tornado on Sunday, 11/17/13. What would have happened if this tornado had hit an area of the state covered in fracking sites? Debris from the tornado has been found over 150 miles away. Imagine if that debris had included "temporarily" stored flowback water or tanks filled with frack fluid or produced water!

Sincerely, Lexington Lawson Chicago, IL 60640

Every county in Illinois has had multiple tornadoes as demonstrated by the maps in the following links:  
<http://www.isws.illinois.edu/atmos/statecli/tornado/ilmaps.htm>  
[http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC\\_Tornado...](http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC_Tornado...) A big swath of Washington, IL was flattened by a tornado on Sunday, 11/17/13. What would have happened if this tornado had hit an area of the state covered in fracking sites? Debris from the tornado has been found over 150 miles away. Imagine if that debris had included "temporarily" stored flowback water or tanks filled with frack fluid or produced water!

Sincerely, Mike Reed Box 421 Sheridan, IL 60551

In reference to Subpart A: General Provisions (245.100-245.120)

Number of draft regulations proposed by Illinois Dept. of Natural Resources describing safety measures regarding tornado strikes on fracking sites: ZERO. Number of tornadoes in Illinois in the last 10 years: 674. Historically, the number and intensity of tornadoes in Illinois is very high. "In fact, Illinois has experienced some of the worst tornadoes in US history." Dr. Jim Angel, Illinois State Climatologist. Every county in Illinois has had multiple tornadoes as demonstrated by the maps in the following links:  
<http://www.isws.illinois.edu/atmos/statecli/tornado/ilmaps.htm>  
[http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC\\_Tornado...](http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC_Tornado...) A big swath of Washington, IL was flattened by a tornado on Sunday, 11/17/13. What would have happened if this tornado had hit an area of the state covered in fracking sites? Debris from the tornado has been found over 150 miles away. Imagine if that debris had included "temporarily" stored flowback water or tanks filled with frack fluid or produced water!

Sincerely, Rebecca Foster Chicago, IL 60615

Every county in Illinois has had multiple tornadoes as demonstrated by the maps in the following links:  
<http://www.isws.illinois.edu/atmos/statecli/tornado/ilmaps.htm>  
[http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC\\_Tornado...](http://www.isws.illinois.edu/atmos/statecli/tornado/NewMaps/MRCC_Tornado...) A big swath of Washington, IL was flattened by a tornado on Sunday, 11/17/13. What would have happened if this tornado had hit an area of the state covered in fracking sites? Debris from the tornado has been found over 150 miles away. Imagine if that debris had included "temporarily" stored flowback water or tanks filled with frack fluid or produced water!

Sincerely, Sean Tyler Chicago, IL 60605

In reference to Subpart A: General Provisions (245.100-245.120)

Problems: 1.The fatality rate of gas and oilfield workers is 7.6 times above all other industries and set an all-time high record in 2012 (King 2013). An inescapably dangerous work setting under the best of circumstances, frack pads are rendered even more dangerous by well operators who eschew workplace safety standards and who force employees to work excessively and dangerously long hours. 2.Sixteen (16) to 20 hour work shifts can be scheduled with the end result that exhausted workers make mistakes in an unforgiving environment or fall asleep behind the wheel of a vehicle, often claiming their own lives and the lives of residents who happen to be on the wrong road at the wrong time (Urbina 2012). 3.There are at least two work related dangers at frack pads that should fall under OSHA regulations: exposure to (1) radiation and (2) silica dust. Both can increase rates of cancer among exposed workers and both kinds of work-site related exposure are limited and regulated by OSHA. Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. Revisions needed: 1.IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. 2.IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Sincerely, Patti Walker RR#2 (Box42a) Karbers Ridge, IL 62955

In reference to Subpart A: General Provisions (245.100-245.120)

Problems: The fatality rate of gas and oilfield workers is 7.6 times above all other industries and set an all-time high record in 2012 (King 2013). An inescapably dangerous work setting under the best of circumstances, frack pads are rendered even more dangerous by well operators who eschew workplace safety standards and who force employees to work excessively and dangerously long hours. Sixteen (16) to 20 hour work shifts can be scheduled with the end result that exhausted workers make mistakes in an unforgiving environment or fall asleep behind the wheel of a vehicle, often claiming their own lives and the lives of residents who happen to be on the wrong road at the wrong time (Urbina 2012). There are at least two work related dangers at frack pads that should fall under OSHA regulations: exposure to (1) radiation and (2) silica dust. Both can increase rates of cancer among exposed workers and both kinds of work-site related exposure are limited and regulated by OSHA. Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. S1-15e of the act gives IDNR the authority collect data, S1-75a2 give the criterion of significant risk and S1-120 gives other applicable laws regarding Hours of Service for Water and Sand Haulers. Yet, the rules do not specify any hours of service rules for sand and wwater delivery truckers; oilfield waiting time exception is for specialty trucks only. The rules also provide nothing on silica exposure tests or meeting OSH Permissible Exposure limites/NIOSH Rec. Exposure limits. Lastly, there are no rules for exposure to radioactivity at all.

Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Sincerely, Abby Dompke Chicago, IL 60607

In reference to Subpart A: General Provisions (245.100-245.120)

Problems: The fatality rate of gas and oilfield workers is 7.6 times above all other industries and set an all-time high record in 2012 (King 2013). An inescapably dangerous work setting under the best of circumstances, frack pads are rendered even more dangerous by well operators who eschew workplace safety standards and who force employees to work excessively and dangerously long hours. Sixteen (16) to 20 hour work shifts can be scheduled with the end result that exhausted workers make mistakes in an unforgiving environment or fall asleep behind the wheel of a vehicle, often claiming their own lives and the lives of residents who happen to be on the wrong road at the wrong time (Urbina 2012). There are at least two work related dangers at frack pads that should fall under OSHA regulations: exposure to (1) radiation and (2) silica dust. Both can increase rates of cancer among exposed workers and both kinds of work-site related exposure are limited and regulated by OSHA. Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Sincerely, Adriana Caballero Oak Park, IL 60302

Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. S1-15e of the act gives IDNR the authority collect data, S1-75a2 give the criterion of significant risk and S1-120 gives other applicable laws regarding Hours of Service for Water and Sand Haulers. Yet, the rules do not specify any hours of service rules for sand and wwater delivery truckers; oilfield waiting time exception is for specialty trucks only. The rules also provide nothing on silica exposure tests or meeting OSH Permissible Exposure limites/NIOSH Rec. Exposure limits. Lastly, there are no rules for exposure to radioactivity at all.

Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Problems: The fatality rate of gas and oilfield workers is 7.6 times above all other industries and set an all-time high record in 2012 (King 2013). An inescapably dangerous work setting under the best of circumstances, frack pads are rendered even more dangerous by well operators who eschew workplace safety standards and who force employees to work excessively and dangerously long hours. Sixteen (16) to 20 hour work shifts can be scheduled with the end result that exhausted workers make mistakes in an unforgiving environment or fall asleep behind the wheel of a vehicle, often claiming their own lives and the lives of residents who happen to be on the wrong road at the wrong time (Urbina 2012). There are at least two work related dangers at frack pads that should fall under OSHA regulations: exposure to (1) radiation and (2) silica dust. Both can increase rates of cancer among exposed workers and both kinds of work-site related exposure are limited and regulated by OSHA. Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. S1-15e of the act gives IDNR the authority collect data, S1-75a2 give the criterion of significant risk and S1-120 gives other applicable laws regarding Hours of Service for Water and Sand Haulers. Yet, the rules do not specify any hours of service rules for sand and wwater delivery truckers; oilfield waiting time exception is for specialty trucks only. The rules also provide nothing on silica exposure tests or meeting OSH Permissible Exposure limites/NIOSH Rec. Exposure limits. Lastly, there are no rules for exposure to radioactivity at all.

Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Sincerely, Anne Pertner Pertner Chicago, IL 60605

In reference to Subpart A: General Provisions (245.100-245.120)

Problems: The fatality rate of gas and oilfield workers is 7.6 times above all other industries and set an all-time high record in 2012 (King 2013). An inescapably dangerous work setting under the best of circumstances, frack pads are rendered even more dangerous by well operators who eschew workplace safety standards and who force employees to work excessively and dangerously long hours. Sixteen (16) to 20 hour work shifts can be scheduled with the end result that exhausted workers make mistakes in an unforgiving environment or fall asleep behind the wheel of a vehicle, often claiming their own lives and the lives of residents who happen to be on the wrong road at the wrong time (Urbina 2012). There are at least two work related dangers at frack pads that should fall under OSHA regulations: exposure to (1) radiation and (2) silica dust. Both can increase rates of cancer among exposed workers and both kinds of work-site related exposure are limited and regulated by OSHA. Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. S1-15e of the act gives IDNR the authority collect data, S1-75a2 give the criterion of significant risk and S1-120 gives other applicable laws regarding Hours of Service for Water and Sand Haulers. Yet, the rules do not specify any hours of service rules for sand and wwater delivery truckers; oilfield waiting time exception is for specialty trucks only. The rules also provide nothing on silica exposure tests or meeting OSH Permissible Exposure limites/NIOSH Rec. Exposure limits. Lastly, there are no rules for exposure to radioactivity at all.

Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

S1-15e of the act gives IDNR the authority collect data, S1-75a2 give the criterion of significant risk and S1-120 gives other applicable laws regarding Hours of Service for Water and Sand Haulers. Yet, the rules do not specify any hours of service rules for sand and wwater delivery truckers; oilfield waiting time exception is for specialty trucks only. The rules also provide nothing on silica exposure tests or meeting OSH Permissible Exposure limites/NIOSH Rec. Exposure limits. Lastly, there are no rules for exposure to radioactivity at all.

Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Sincerely, E Zemin Champaign, IL 61821

In reference to Subpart A: General Provisions (245.100-245.120)

Problems: The fatality rate of gas and oilfield workers is 7.6 times above all other industries and set an all-time high record in 2012 (King 2013). An inescapably dangerous work setting under the best of circumstances, frack pads are rendered even more dangerous by well operators who eschew workplace safety standards and who force employees to work excessively and dangerously long hours. Sixteen (16) to 20 hour work shifts can be scheduled with the end result that exhausted workers make mistakes in an unforgiving environment or fall asleep behind the wheel of a vehicle, often claiming their own lives and the lives of residents who happen to be on the wrong road at the wrong time (Urbina 2012). There are at least two work related dangers at frack pads that should fall under OSHA regulations: exposure to (1) radiation and (2) silica dust. Both can increase rates of cancer among exposed workers and both kinds of work-site related exposure are limited and regulated by OSHA. Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. S1-15e of the act gives IDNR the authority collect data, S1-75a2 give the criterion of significant risk and S1-120 gives other applicable laws regarding Hours of Service for Water and Sand Haulers. Yet, the rules do not specify any hours of service rules for sand and wwater delivery truckers; oilfield waiting time exception is for specialty trucks only. The rules also provide nothing on silica exposure tests or meeting OSH Permissible Exposure limites/NIOSH Rec. Exposure limits. Lastly, there are no rules for exposure to radioactivity at all.

Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Problems: The fatality rate of gas and oilfield workers is 7.6 times above all other industries and set an all-time high record in 2012 (King 2013). An inescapably dangerous work setting under the best of circumstances, frack pads are rendered even more dangerous by well operators who eschew workplace safety standards and who force employees to work excessively and dangerously long hours. Sixteen (16) to 20 hour work shifts can be scheduled with the end result that exhausted workers make mistakes in an unforgiving environment or fall asleep behind the wheel of a vehicle, often claiming their own lives and the lives of residents who happen to be on the wrong road at the wrong time (Urbina 2012). There are at least two work related dangers at frack pads that should fall under OSHA regulations: exposure to (1) radiation and (2) silica dust. Both can increase rates of cancer among exposed workers and both kinds of work-site related exposure are limited and regulated by OSHA. Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. S1-15e of the act gives IDNR the authority collect data, S1-75a2 give the criterion of significant risk and S1-120 gives other applicable laws regarding Hours of Service for Water and Sand Haulers. Yet, the rules do not specify any hours of service rules for sand and wwater delivery truckers; oilfield waiting time exception is for specialty trucks only. The rules also provide nothing on silica exposure tests or meeting OSH Permissible Exposure limites/NIOSH Rec. Exposure limits. Lastly, there are no rules for exposure to radioactivity at all.

Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Sincerely, Girwana Baker Chicago, IL 60605

Problems: The fatality rate of gas and oilfield workers is 7.6 times above all other industries and set an all-time high record in 2012 (King 2013). An inescapably dangerous work setting under the best of circumstances, frack pads are rendered even more dangerous by well operators who eschew workplace safety standards and who force employees to work excessively and dangerously long hours. Sixteen (16) to 20 hour work shifts can be scheduled with the end result that exhausted workers make mistakes in an unforgiving environment or fall asleep behind the wheel of a vehicle, often claiming their own lives and the lives of residents who happen to be on the wrong road at the wrong time (Urbina 2012). There are at least two work related dangers at frack pads that should fall under OSHA regulations: exposure to (1) radiation and (2) silica dust. Both can increase rates of cancer among exposed workers and both kinds of work-site related exposure are limited and regulated by OSHA. Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. S1-15e of the act gives IDNR the authority collect data, S1-75a2 give the criterion of significant risk and S1-120 gives other applicable laws regarding Hours of Service for Water and Sand Haulers. Yet, the rules do not specify any hours of service rules for sand and wwater delivery truckers; oilfield waiting time exception is for specialty trucks only. The rules also provide nothing on silica exposure tests or meeting OSH Permissible Exposure limites/NIOSH Rec. Exposure limits. Lastly, there are no rules for exposure to radioactivity at all.

Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Sincerely, Jessa Dahl Chicago, IL 60615

Yet, the rules do not specify any hours of service rules for sand and wwater delivery truckers; oilfield waiting time exception is for specialty trucks only. The rules also provide nothing on silica exposure tests or meeting OSH Permissible Exposure limites/NIOSH Rec. Exposure limits. Lastly, there are no rules for exposure to radioactivity at all.

Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Sincerely, Jorge Sanchez Chicago, IL 60637

In reference to Subpart A: General Provisions (245.100-245.120)

Problems: The fatality rate of gas and oilfield workers is 7.6 times above all other industries and set an all-time high record in 2012 (King 2013). An inescapably dangerous work setting under the best of circumstances, frack pads are rendered even more dangerous by well operators who eschew workplace safety standards and who force employees to work excessively and dangerously long hours. Sixteen (16) to 20 hour work shifts can be scheduled with the end result that exhausted workers make mistakes in an unforgiving environment or fall asleep behind the wheel of a vehicle, often claiming their own lives and the lives of residents who happen to be on the wrong road at the wrong time (Urbina 2012). There are at least two work related dangers at frack pads that should fall under OSHA regulations: exposure to (1) radiation and (2) silica dust. Both can increase rates of cancer among exposed workers and both kinds of work-site related exposure are limited and regulated by OSHA. Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. S1-15e of the act gives IDNR the authority collect data, S1-75a2 give the criterion of significant risk and S1-120 gives other applicable laws regarding Hours of Service for Water and Sand Haulers. Yet, the rules do not specify any hours of service rules for sand and wwater delivery truckers; oilfield waiting time exception is for specialty trucks only. The rules also provide nothing on silica exposure tests or meeting OSH Permissible Exposure limites/NIOSH Rec. Exposure limits. Lastly, there are no rules for exposure to radioactivity at all.

Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Sincerely, Kelsey Bratanch itasca, IL 60143

In reference to Subpart A: General Provisions (245.100-245.120)

Problems: The fatality rate of gas and oilfield workers is 7.6 times above all other industries and set an all-time high record in 2012 (King 2013). An inescapably dangerous work setting under the best of circumstances, frack pads are rendered even more dangerous by well operators who eschew workplace safety standards and who force employees to work excessively and dangerously long hours. Sixteen (16) to 20 hour work shifts can be scheduled with the end result that exhausted workers make mistakes in an unforgiving environment or fall asleep behind the wheel of a vehicle, often claiming their own lives and the lives of residents who happen to be on the wrong road at the wrong time (Urbina 2012). There are at least two work related dangers at frack pads that should fall under OSHA regulations: exposure to (1) radiation and (2) silica dust. Both can increase rates of cancer among exposed workers and both kinds of work-site related exposure are limited and regulated by OSHA. Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. S1-15e of the act gives IDNR the authority collect data, S1-75a2 give the criterion of significant risk and S1-120 gives other applicable laws regarding Hours of Service for Water and Sand Haulers. Yet, the rules do not specify any hours of service rules for sand and wwater delivery truckers; oilfield waiting time exception is for specialty trucks only. The rules also provide nothing on silica exposure tests or meeting OSH Permissible Exposure limites/NIOSH Rec. Exposure limits. Lastly, there are no rules for exposure to radioactivity at all.

Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Sincerely, Kelsey Chicago, IL 60631

Yet, the rules do not specify any hours of service rules for sand and wwater delivery truckers; oilfield waiting time exception is for specialty trucks only. The rules also provide nothing on silica exposure tests or meeting OSH Permissible Exposure limites/NIOSH Rec. Exposure limits. Lastly, there are no rules for exposure to radioactivity at all.

Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.

Sincerely, Luke Dobbs Chicago, IL 60605

In reference to Subpart A: General Provisions (245.100-245.120)

Problems: The fatality rate of gas and oilfield workers is 7.6 times above all other industries and set an all-time high record in 2012 (King 2013). An inescapably dangerous work setting under the best of circumstances, frack pads are rendered even more dangerous by well operators who eschew workplace safety standards and who force employees to work excessively and dangerously long hours. Sixteen (16) to 20 hour work shifts can be scheduled with the end result that exhausted workers make mistakes in an unforgiving environment or fall asleep behind the wheel of a vehicle, often claiming their own lives and the lives of residents who happen to be on the wrong road at the wrong time (Urbina 2012). There are at least two work related dangers at frack pads that should fall under OSHA regulations: exposure to (1) radiation and (2) silica dust. Both can increase rates of cancer among exposed workers and both kinds of work-site related exposure are limited and regulated by OSHA. Yet, the oil and gas industry have found an easy way to escape regulation: simply don't test for work place exposure. Since there are no data on exposure, OSHA cannot step in and demand workplace fixes. S1-15e of the act gives IDNR the authority collect data, S1-75a2 give the criterion of significant risk and S1-120 gives other applicable laws regarding Hours of Service for Water and Sand Haulers. Yet, the rules do not specify any hours of service rules for sand and wwater delivery truckers; oilfield waiting time exception is for specialty trucks only. The rules also provide nothing on silica exposure tests or meeting OSH Permissible Exposure limites/NIOSH Rec. Exposure limits. Lastly, there are no rules for exposure to radioactivity at all.

Revisions needed: IDNR must require fracking operators to adhere to OSHA rule and regulations, especially regarding dust and radioactivity. IDNR must develop rules which recognize and regulate non-union frack operations to address inherently dangerous workplace conditions, including but not limited to work shifts, working conditions, and truck transportation to and from operations.
